Nuclear Physics

What to do in this course:

- I. Read the relevant sections in the textbook
... the course notes will guide you.
2. Do all homework and problem sets.
3. Get help early ... from Course Teacher.
4. there are no shortcuts ... put effort in to understand things ...

Problem-solving and homework

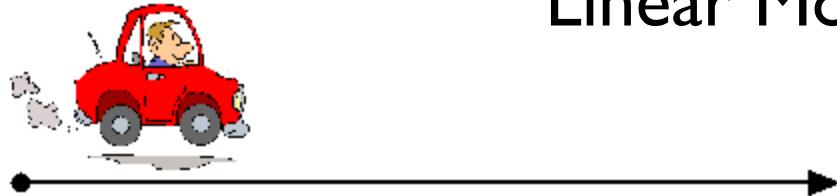

Each Chapter you will be given a take-home problem set to complete and hand in for marks ... In addition to this, you need to work through the problems in *Book, in your own time, at home.*

You will not be asked to hand these in for marks. Get help from your friends, the course Teacher ...

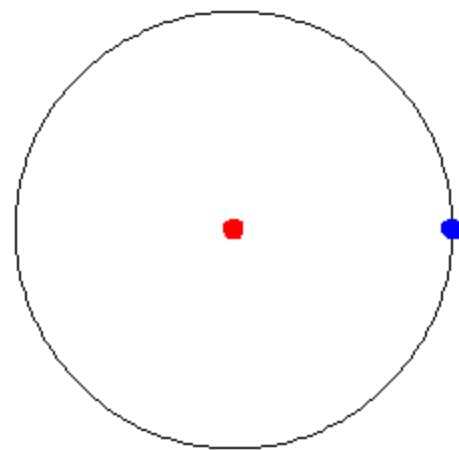

Do not take shortcuts. Mastering these problems is a fundamental aspect of this course.

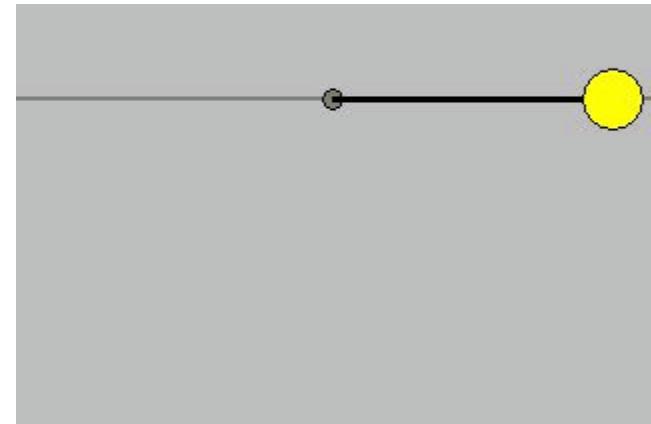

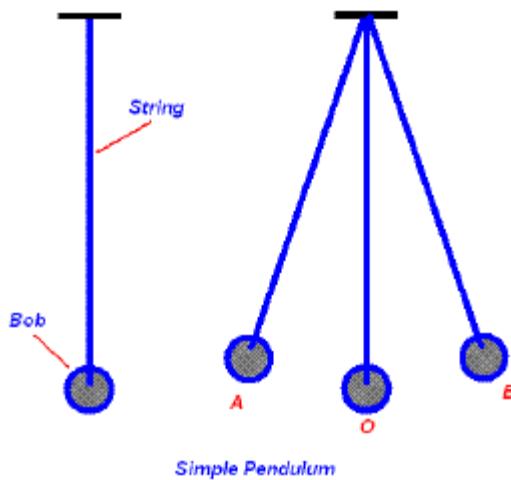

Different Kind of Motions

Linear Motion

Uniform Circular Motion

Oscillatory Motion (Simple Pendulum)

Oscillatory Motion (Spring Mass)

Oscillatory Phenomena

... observed in many physical systems ...
from the very small...(e.g. dipole resonance in nuclei)... to the very large (earthquake waves, stars,...)

Mechanical systems to lasers
..... from violin strings to electrical systems

Oscillatory Motion

Motion which is periodic in time, that is, motion that repeats itself in time.

Examples:

- Power line oscillates when the wind blows past it
- Earthquake oscillations move buildings

- Block attached to a spring
- Motion of a swing
- Motion of a pendulum
- Vibrations of a stringed musical instrument
- Motion of a cantilever
- Oscillations of houses, bridges, ...
- All clocks use simple harmonic motion

Periodic Motion: Many kind of motion repeat over and over, such as, the vibrations of quartz crystal in a watch, swinging pendulum in a clock and back-and-forth motion of a piston in an engine. This kind of motions are called periodic motion.

Amplitude: The amplitude of the motion, denoted by A , is the maximum magnitude of displacement from the equilibrium position. It is always positive

Period: The period T , is the time required for one oscillation.

Frequency: The frequency, f , is the number of cycles in a unit time.

Simple Harmonic Motion:

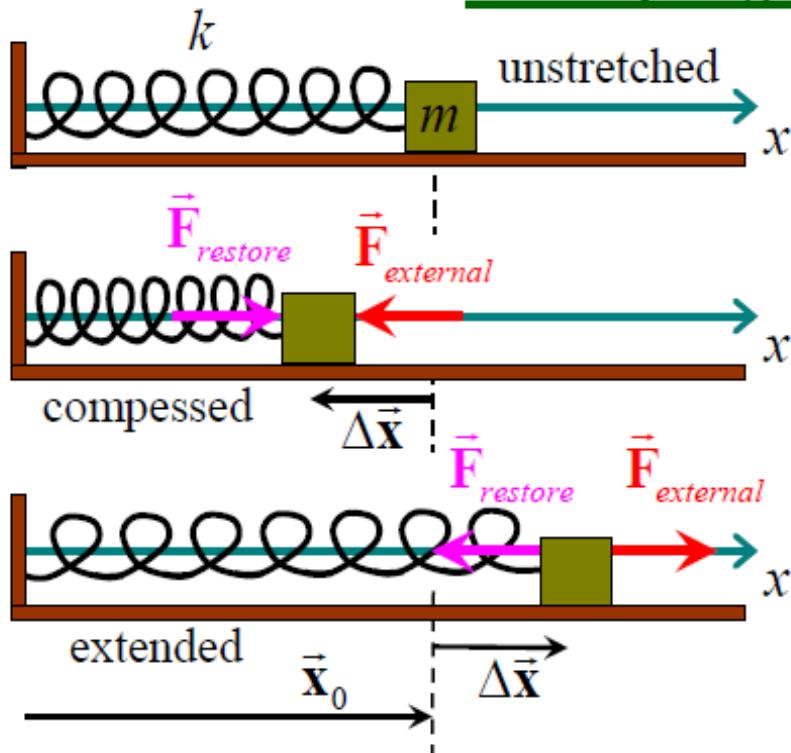

The simplest kind of oscillation occurs when the restoring force F_x is directly proportional to the displacement from the equilibrium x .

When the restoring force is directly proportional to the displacement from the equilibrium as given by equation

$$F_x = -kx$$

The oscillation is called Simple Harmonic Motion(SHM).

Mass-spring oscillator

Hooke's Law:

Restoring force,

$$\vec{F}_{restore} = -k\Delta\vec{x}$$

$$\text{where } \Delta\vec{x} = \vec{x} - \vec{x}_0$$

and k is the “spring constant”
[N m⁻¹]

Start with the
momentum principle: $\frac{d\vec{p}}{dt} = \vec{F}_{net}$

For horizontal forces on the mass: $\frac{dp_x}{dt} = -kx$

$$\therefore \frac{d(mv_x)}{dt} = -kx \quad \text{or} \quad \frac{d}{dt} \left(m \frac{dx}{dt} \right) = -kx$$

$$\therefore \frac{d^2x}{dt^2} = -\frac{k}{m}x \quad 9$$

Mass-spring oscillator ...2

$$\frac{d^2x(t)}{dt^2} = \frac{-k}{m}x(t)$$

... a second order differential equation
... we know that if we displace a mass-spring system from its rest position and then release it, it will perform SHM ...

Guess a trial solution: $x(t) = A \cos(\omega t + \phi)$

then $\frac{d^2x}{dt^2} = -A\omega^2 \cos(\omega t + \phi)$

and substitute into our DE: $-A\omega^2 \cos(\omega t + \phi) = -A \frac{k}{m} \cos(\omega t + \phi)$

... which is true provided $\omega^2 = \frac{k}{m}$

Therefore our solution is $x(t) = A \cos(\omega t + \phi)$ where $\omega = \sqrt{\frac{k}{m_{10}}}$

Mass-spring oscillator ...3

We will write a particular value of ω as ω_0 , as the **natural angular frequency** of the oscillator – the frequency that it “wants” to oscillate at.

Mass-spring system: $\omega_0 = \sqrt{\frac{k}{m}}$ and $T = 2\pi\sqrt{\frac{m}{k}}$

System parameters: $m, k \longrightarrow \omega_0$

Initial conditions: $\longrightarrow A, \phi$

(Note that ω_0 is independent of A)

Simple harmonic oscillator

$$x(t) = A \cos(\omega_0 t + \phi)$$

$$v(t) = \frac{dx(t)}{dt} = -A\omega_0 \sin(\omega_0 t + \phi)$$

$$a(t) = \frac{d^2x(t)}{dt^2} = \frac{dv(t)}{dt} = -A\omega_0^2 \cos(\omega_0 t + \phi)$$

... acceleration = - (constant) . (displacement)

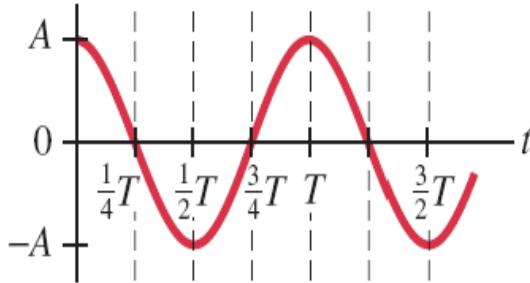

$$= -A\omega_0^2 \cos(\omega_0 t + \phi)$$

$$= A\omega_0^2 \cos(\omega_0 t + \phi + \pi)$$

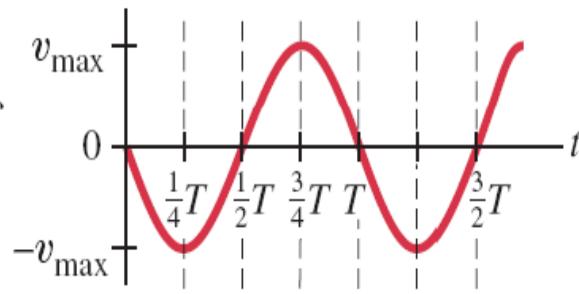

Phase difference between acceleration and displacement is π

Phase difference between v and x (and v & a) is $\frac{\pi}{2}$

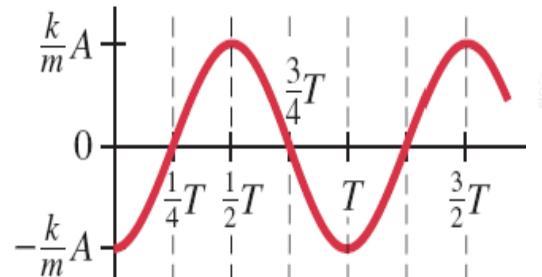

Displacement x

Velocity v

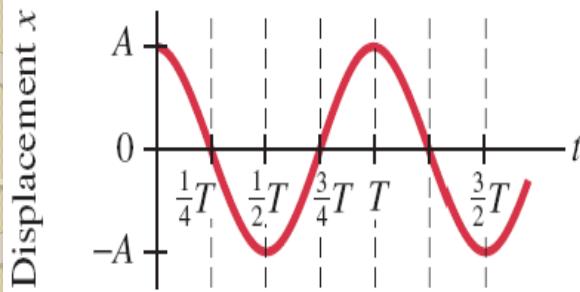

Acceleration a

The velocity and acceleration for simple harmonic motion can be found by differentiating the displacement:

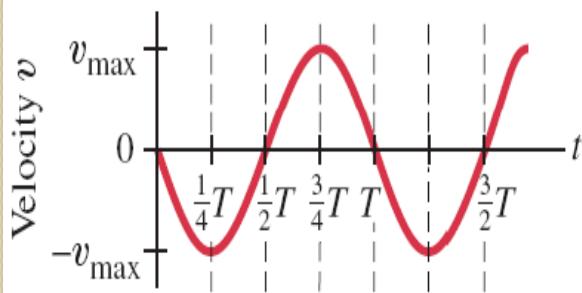

$$v = \frac{dx}{dt} = -\omega A \sin(\omega t + \phi)$$

$$a = \frac{d^2x}{dt^2} = \frac{dv}{dt} = -\omega^2 A \cos(\omega t + \phi).$$

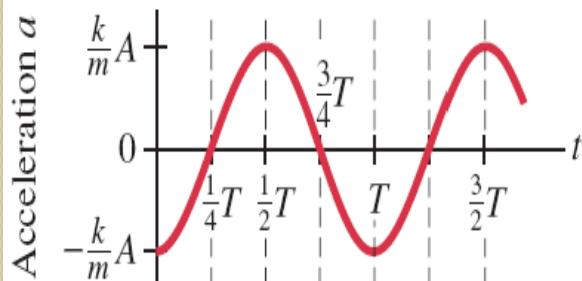

$$x = A \cos(\omega t + f),$$

$$v = -\omega A \sin(\omega t + f)$$

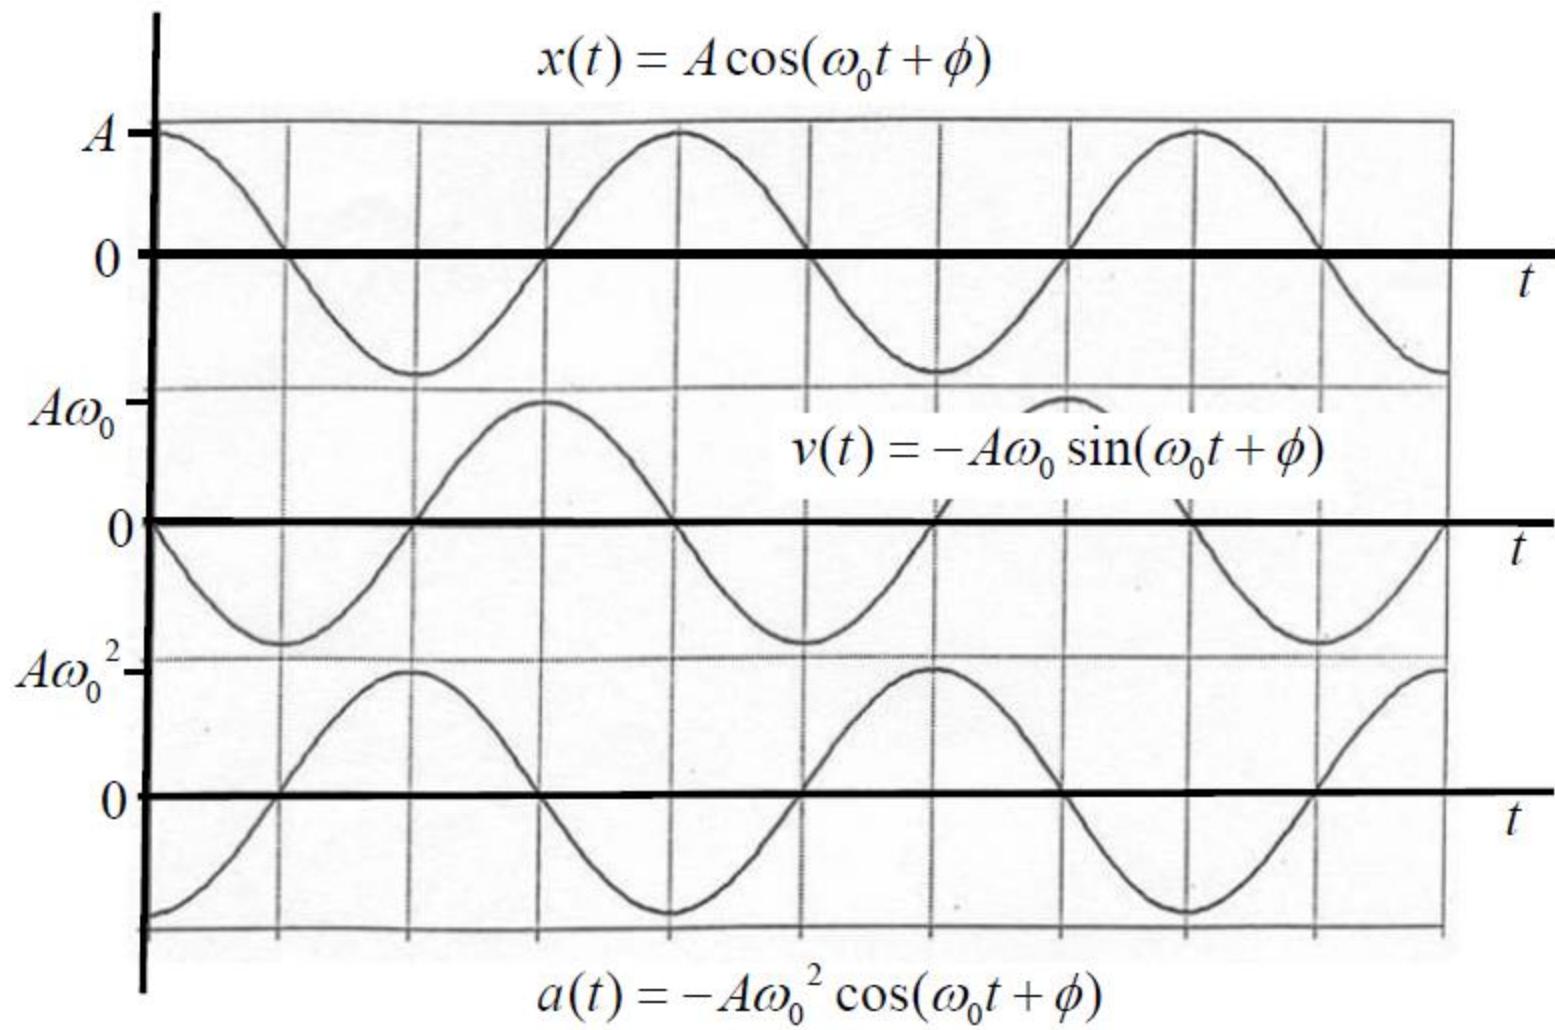

$$= \omega A \cos(\omega t + f + \frac{\rho}{2}),$$

$$a = -\omega^2 A \cos(\omega t + f)$$

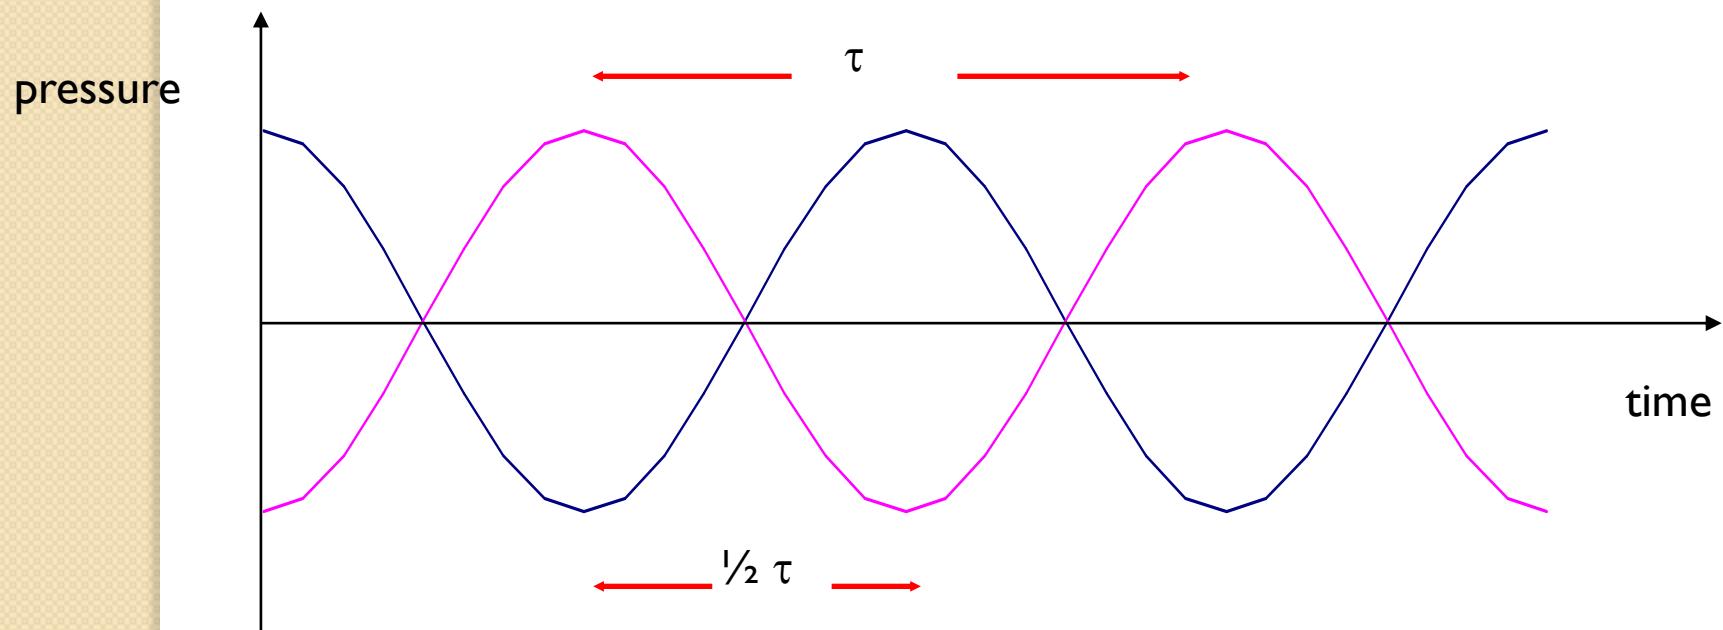

$$= -\omega^2 A \sin(\omega t + f + \frac{\rho}{2}).$$

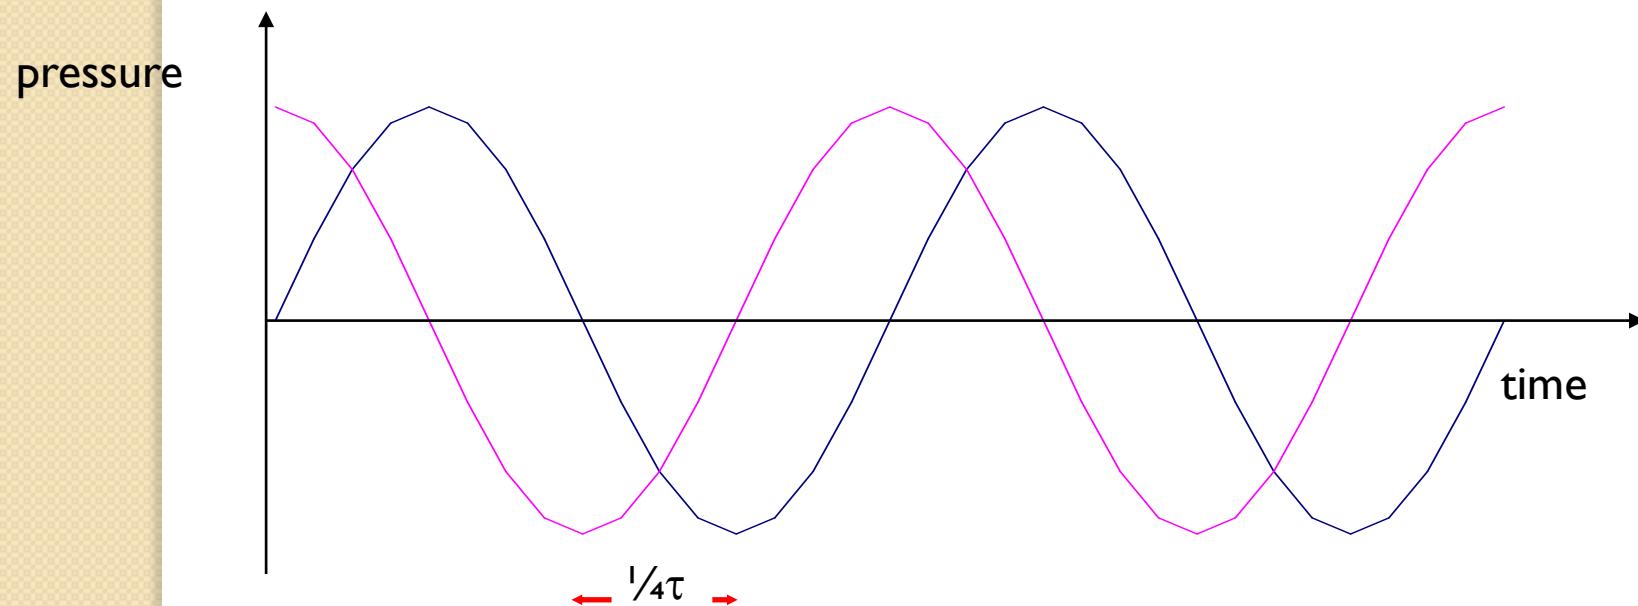

Phase Difference

- The phase of periodic wave describes where the wave is in its cycle
- Phase difference is used to describe the phase position of one wave relative to another

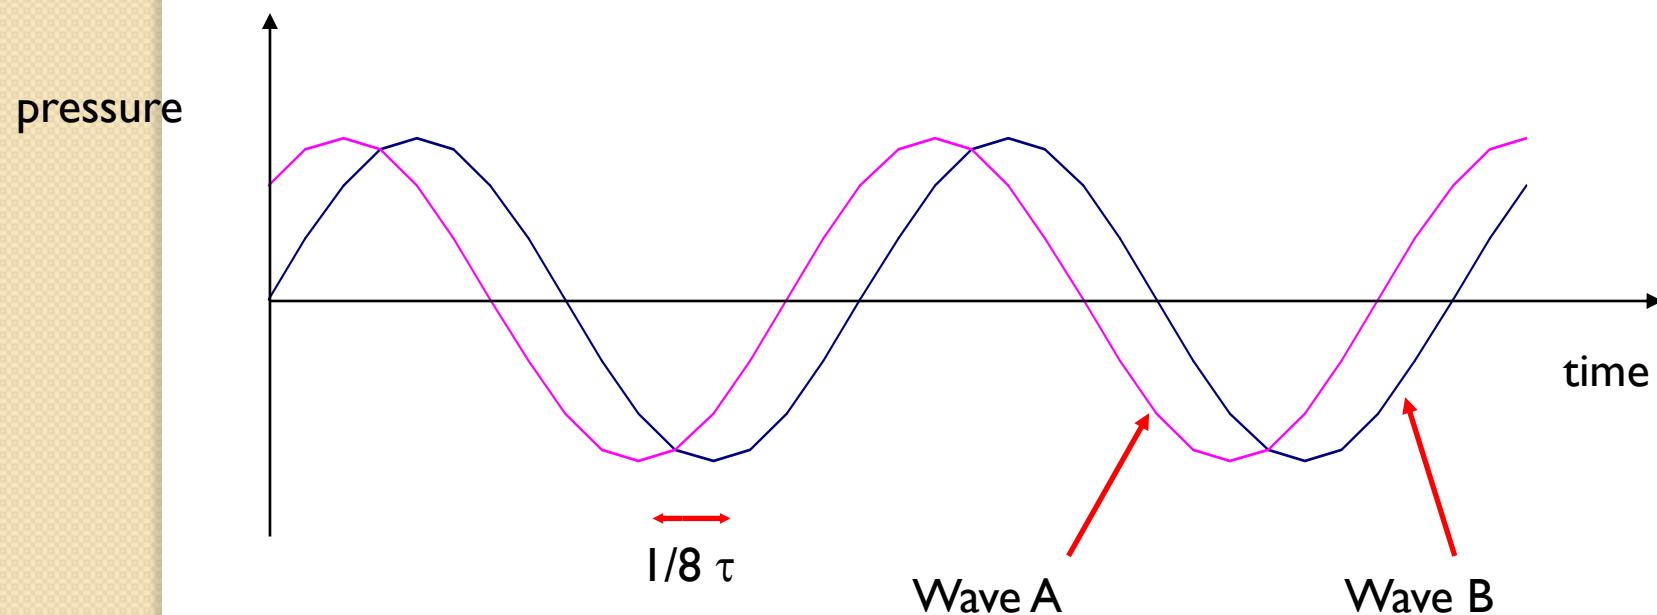

Phase Difference 180°

Phase Difference 90°

Phase Difference 45°

Simple harmonic oscillator

At $t = 0$, write $x = x_0$ and $v = v_0$.

Then at $t = 0$:

$$\left. \begin{array}{l} x_0 = A \cos(\phi) \\ v_0 = -\omega_0 A \sin(\phi) \end{array} \right\} \tan \phi = -\frac{v_0}{\omega_0 x_0}$$

... and $x_0^2 + \left(\frac{v_0}{\omega_0} \right)^2 = A^2 \cos^2(\phi) + A^2 \sin^2(\phi) = A^2$

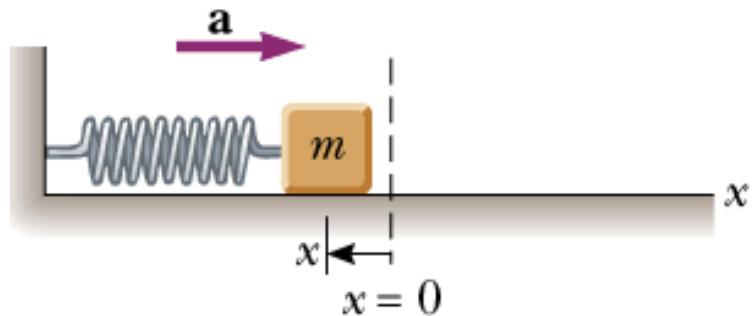

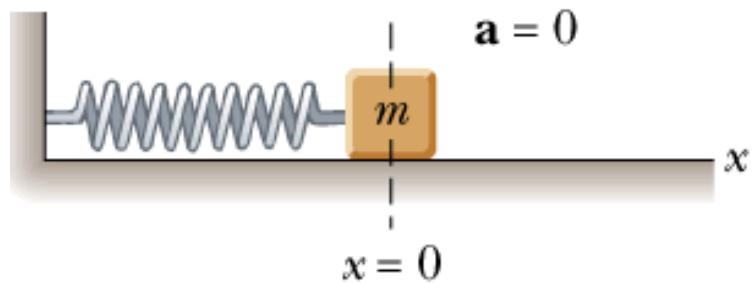

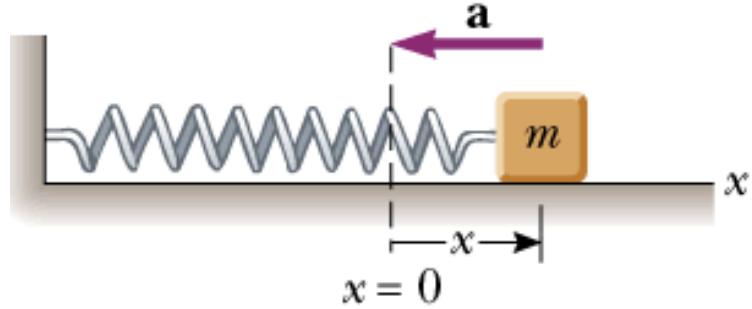

$$\therefore A = \sqrt{x_0^2 + \left(\frac{v_0}{\omega_0} \right)^2}$$

Ex. A block of mass 680gm is fastened to a spring of spring constant 65N/m. The block is pulled a distance 11cm from its equilibrium on a frictionless table and released

- (a) What are the angular frequency, the frequency, and the period of the motion?
- (b) What is amplitude of the motion?
- (c) What is the maximum speed of the block?

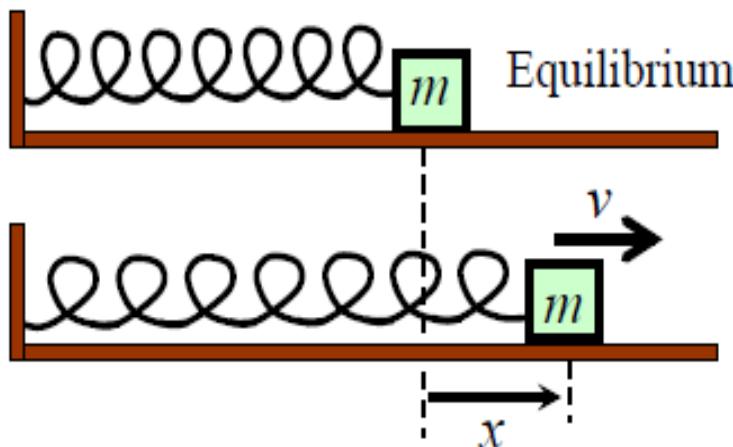

Example

A spring stretches by 3.90 cm when a 10.0 g mass is hung from it. A 25.0 g mass attached to this spring oscillates in simple harmonic motion.

- Calculate the period of the motion.
- Calculate frequency and the angular velocity of the motion.

Mass-spring oscillator: an energy approach

Suppose that the mass has a speed v when it has displacement x

Kinetic energy of mass = $\frac{1}{2}mv^2$

Potential energy of spring = $\int_0^x F dx' = \int_0^x kx' dx' = \frac{1}{2}kx^2$

There are no dissipative mechanisms in our model (no friction).
... the total energy of the mass-spring system is conserved.

$$\frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \text{constant}$$

Mass-spring oscillator: an energy approach ...2

For our mass-spring system: $\frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \text{constant}$

$$\therefore \frac{d}{dt} \left(\frac{1}{2}mv^2 + \frac{1}{2}kx^2 \right) = 0$$

$$\therefore mv \frac{dv}{dt} + kx \frac{dx}{dt} = 0$$

$$\therefore mv \frac{dv}{dt} + kxv = 0$$

$$\therefore m \frac{dv}{dt} + kx = 0$$

$$\therefore \frac{d^2x}{dt^2} = -\frac{k}{m}x$$

... as before

Mass-spring oscillator: an energy approach ...3

For the mass-spring system: $x = A \cos(\omega_0 t + \phi)$

$$\text{Potential energy} = \frac{1}{2} kx^2 = \frac{1}{2} kA^2 \cos^2(\omega_0 t + \phi)$$

$$\text{k.e.} = \frac{1}{2} mv^2 = \frac{1}{2} m[-A\omega_0 \sin(\omega_0 t + \phi)]^2 = \frac{1}{2} mA^2 \omega_0^2 \sin^2(\omega_0 t + \phi)$$

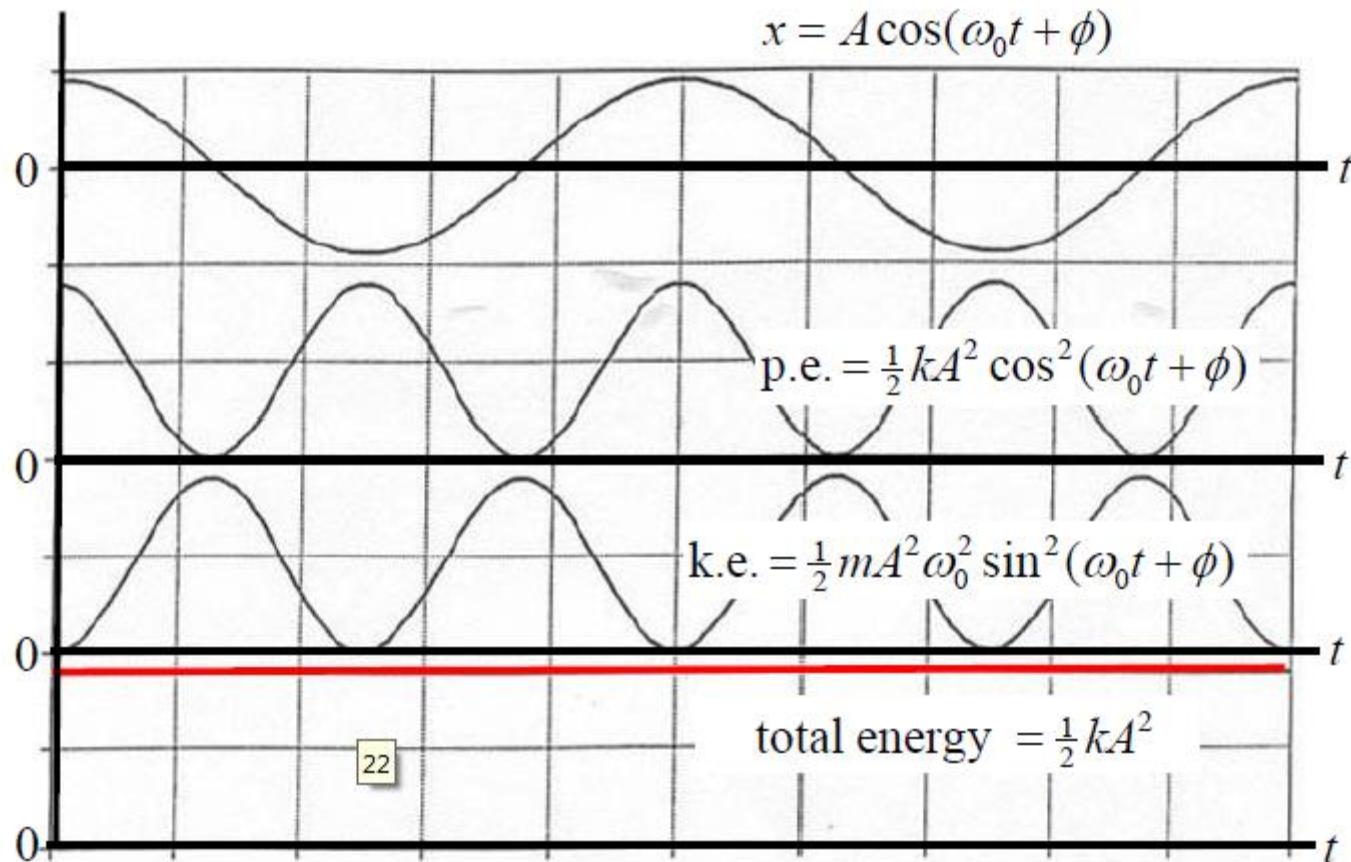

Total energy = p.e. + k.e

$$\begin{aligned} &= \frac{1}{2} kA^2 \cos^2(\omega_0 t + \phi) + \frac{1}{2} mA^2 \omega_0^2 \sin^2(\omega_0 t + \phi) \\ &= \frac{1}{2} kA^2 \quad (= \frac{1}{2} m\omega_0^2 A^2) \quad (\because E \propto A^2) \end{aligned}$$

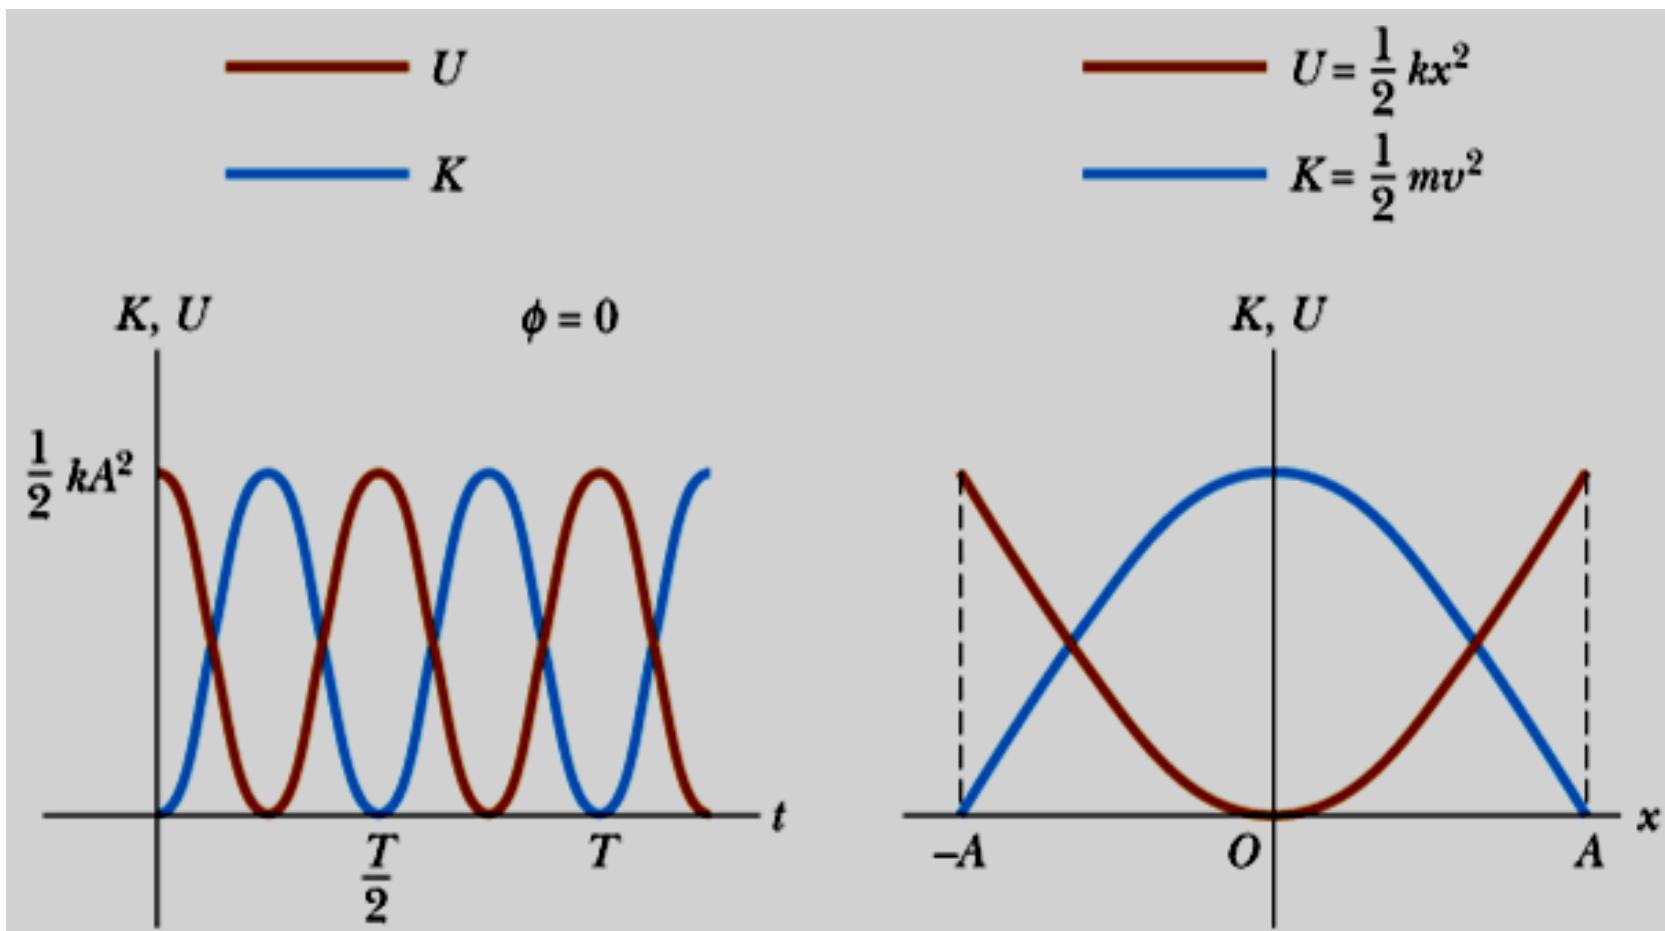

We can now write: $\frac{1}{2} kx^2 + \frac{1}{2} mv^2 = \frac{1}{2} kA^2$

$$\therefore v = \pm \sqrt{\frac{k}{m}(A^2 - x^2)} \quad \text{or} \quad v(x) = \pm \omega_0 \sqrt{A^2 - x^2} \quad (\text{useful})$$

Energy of the mass-spring simple harmonic oscillator

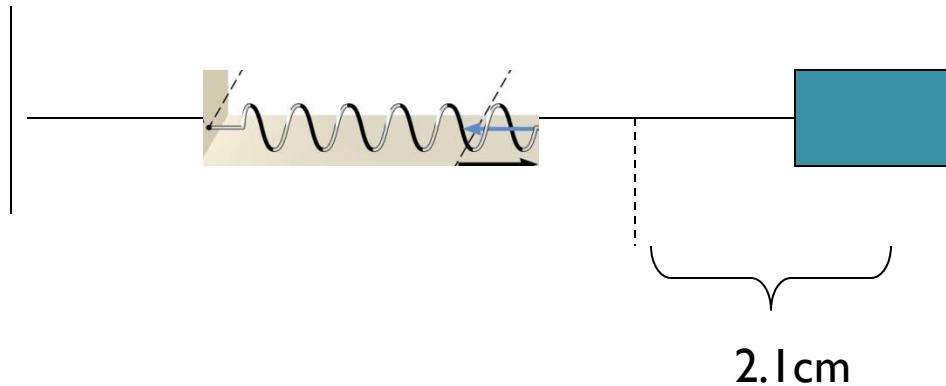

K.E and P.E of SHM

Check Your Understanding

A 0.42-kg block is attached to the end of a horizontal ideal spring and rests on a frictionless surface. The block is pulled so that the spring stretches by 2.1 cm relative to its unstrained length. When the block is released, it moves with an acceleration of 9.0 m/s². What is the spring constant of the spring?

180 N/m

$$kx = ma$$

$$k \times \frac{2.1}{100} = 0.42 \times 9.0 m/s^2$$

$$k = \frac{0.42 \times 9.0}{2.1} \times 100 = 180 N/m$$

Energy in the SHO

Energy calculations.

For the simple harmonic oscillation where $k = 19.6 \text{ N/m}$, $A = 0.100 \text{ m}$, $x = -(0.100 \text{ m}) \cos 8.08t$, and $v = (0.808 \text{ m/s}) \sin 8.08t$, determine (a) the total energy, (b) the kinetic and potential energies as a function of time, (c) the velocity when the mass is 0.050 m from equilibrium, (d) the kinetic and potential energies at half amplitude ($x = \pm A/2$).

Solution:

a. $E = \frac{1}{2}kA^2 = \frac{1}{2} \times 19.6 \text{ N/m} \times (0.100 \text{ m})^2 = 9.80 \times 10^{-2} \text{ J.}$

b. $U = \frac{1}{2}kx^2 = \frac{1}{2}kA^2 \cos^2 \omega t = (9.80 \times 10^{-2} \text{ J}) \cos^2 8.08t,$

$$K = E - U = (9.80 \times 10^{-2} \text{ J}) \sin^2 8.08t.$$

Solution:

c. $K = E - U, \quad \frac{1}{2}mv^2 = \frac{1}{2}kA^2 - \frac{1}{2}kx^2,$

$$v = \sqrt{\frac{k}{m}(A^2 - x^2)} = \omega\sqrt{A^2 - x^2}$$
$$= 8.08\text{Hz} \times \sqrt{(0.100\text{m})^2 - (0.050\text{m})^2} = 0.70\text{m/s.}$$

d. $U = \frac{1}{2}kx^2 = \frac{1}{2}k\zeta \frac{x}{2\theta}^2 = \frac{1}{4}E = 2.5 \times 10^{-2}\text{J},$

$$E = K - U = 7.3 \times 10^{-2}\text{J.}$$

Example:

Using Conservation of Energy

A 500 g block on a spring is pulled a distance of 20 cm and released. The subsequent oscillations are measured to have a period of 0.80 s. At what position (or positions) is the speed of the block 1.0 m/s?

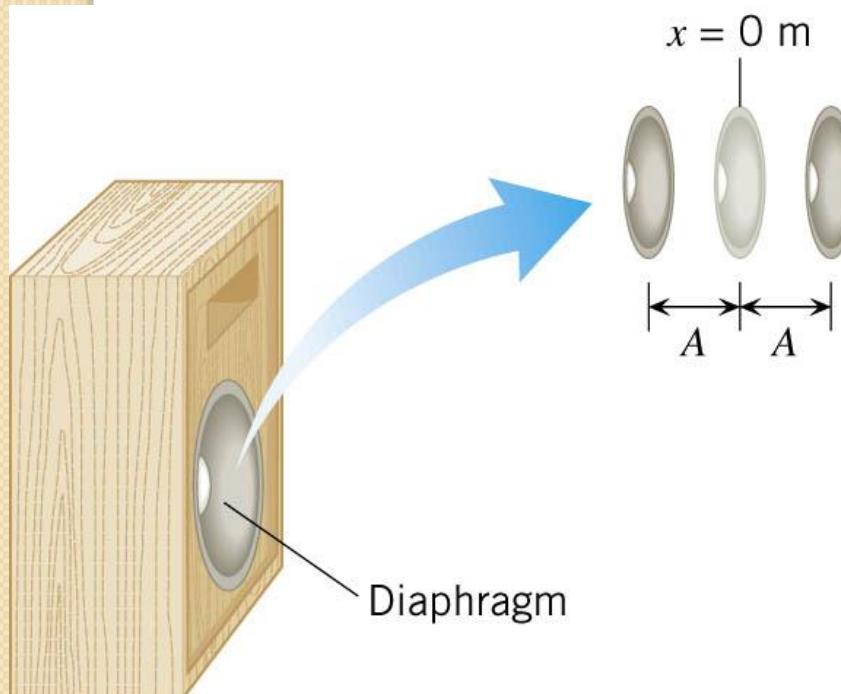

$$T = 0.80 \text{ s} \text{ so } \omega = \frac{2\pi}{T} = \frac{2\pi}{(0.80 \text{ s})} = 7.85 \text{ rad/s}$$

$$v = \sqrt{\frac{k}{m}(A^2 - x^2)} = \omega \sqrt{A^2 - x^2}$$

$$x = \pm \sqrt{A^2 - \left(\frac{v}{\omega}\right)^2} = \pm \sqrt{(0.20 \text{ m})^2 - \left(\frac{(1.0 \text{ m/s})}{(7.85 \text{ rad/s})}\right)^2} = \pm 0.154 \text{ m} = \pm 15.4 \text{ cm}$$

Example: The Maximum Speed of a Loudspeaker Diaphragm

The diaphragm of a loudspeaker moves back and forth in simple harmonic motion to create sound. The frequency of the motion is $f = 1.0 \text{ kHz}$ and the amplitude is $A = 0.20 \text{ mm}$.

- (a) What is the maximum speed of the diaphragm?
- (b) Where in the motion does this maximum speed occur?

(a)

$$v_{\max} = A\omega = A(2\pi f) = (0.20 \times 10^{-3} \text{ m})(2\pi)(1.0 \times 10^3 \text{ Hz}) = \boxed{1.3 \text{ m/s}}$$

(b) The speed of the diaphragm is zero when the diaphragm momentarily comes to rest at either end of its motion: $x = +A$ and $x = -A$. Its maximum speed occurs midway between these two positions, or at $x = 0 \text{ m}$.

Example: Radio Station Frequency and Period

What is the oscillation period of an FM radio station that broadcasts at 100 MHz?

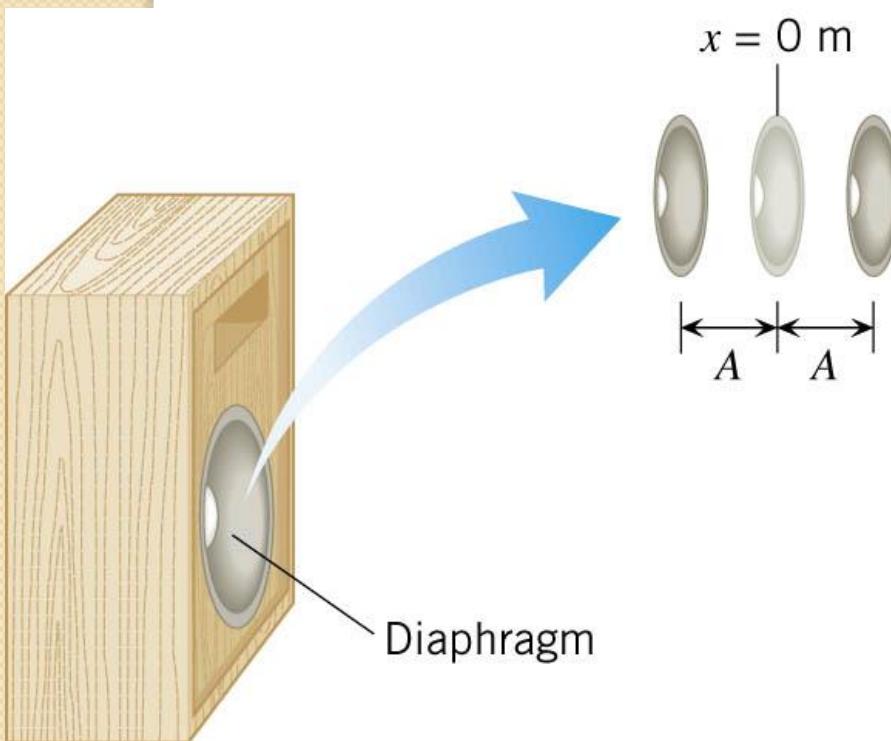

$$f = 100 \text{ MHz} = 1.0 \times 10^8 \text{ Hz}$$

$$T = 1/f = \frac{1}{1.0 \times 10^8 \text{ Hz}} = 1.0 \times 10^{-8} \text{ s} = 10 \text{ ns}$$

Note that $1/\text{Hz} = \text{s}$

Example :

The Loudspeaker Revisited—The Maximum Acceleration

A loudspeaker diaphragm is vibrating at a frequency of $f = 1.0 \text{ kHz}$, and the amplitude of the motion is $A = 0.20 \text{ mm}$.

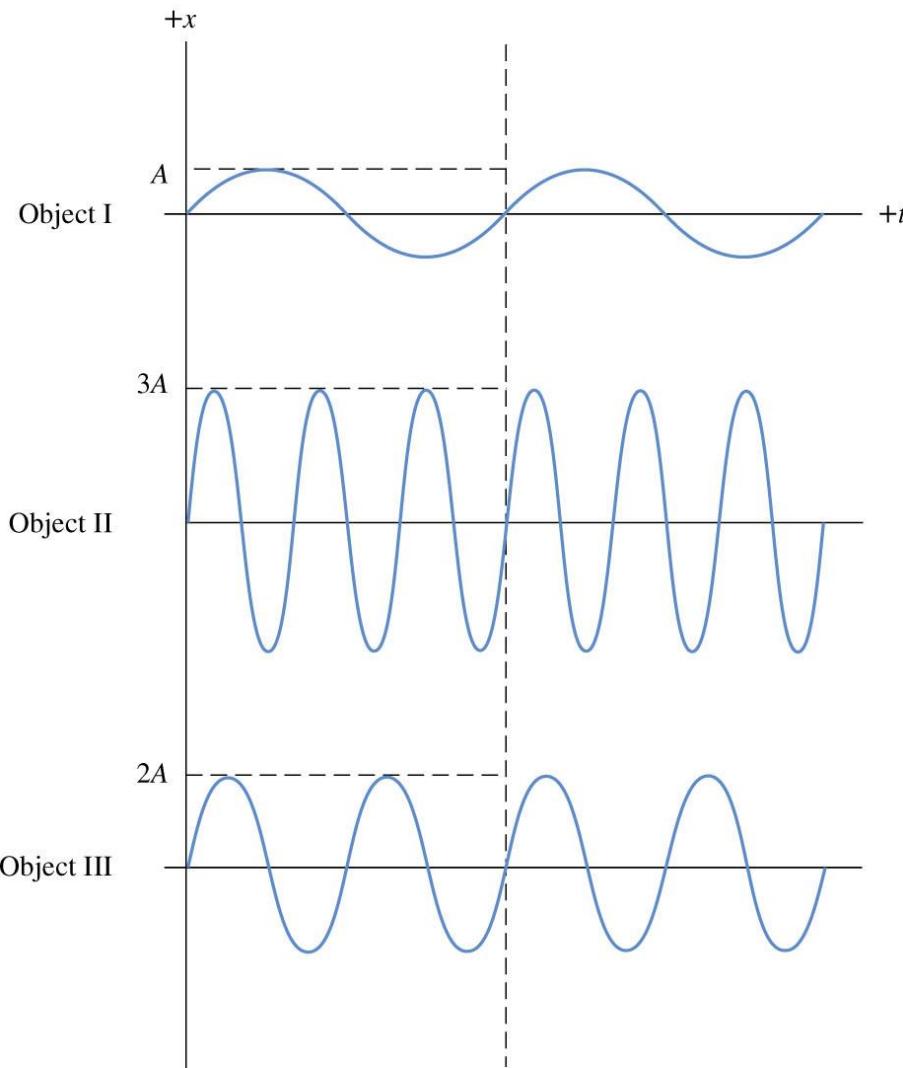

- What is the maximum acceleration of the diaphragm, and
- where does this maximum acceleration occur?

(a)

$$a_{\max} = A\omega^2 = A(2\pi f)^2 = (0.20 \times 10^{-3} \text{ m}) [2\pi(1.0 \times 10^3 \text{ Hz})]^2$$
$$= \boxed{7.9 \times 10^3 \text{ m/s}^2}$$

(b) **the maximum acceleration occurs at $x = +A$ and $x = -A$**

Check Your Understanding

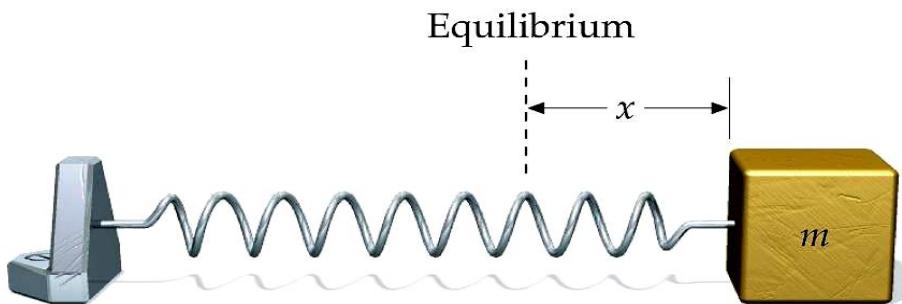

The drawing shows plots of the displacement x versus the time t for three objects undergoing simple harmonic motion. Which object, I, II, or III, has the greatest maximum velocity?

II

Example: A Block on a Spring

A 2.00 kg block is attached to a spring as shown. The force constant of the spring is $k = 196 \text{ N/m}$. The block is held a distance of 5.00 cm from equilibrium and released at $t = 0$.

- Find the angular frequency ω , the frequency f , and the period T .
- Write an equation for x vs. time.

$$\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{(196 \text{ N/m})}{(2.00 \text{ kg})}} = 9.90 \text{ rad/s}$$

$$f = \frac{\omega}{2\pi} = \frac{(9.90 \text{ rad/s})}{2\pi} = 1.58 \text{ Hz}$$

$$T = 1/f = 0.635 \text{ s} \quad A = 5.00 \text{ cm} \text{ and } \delta = 0$$

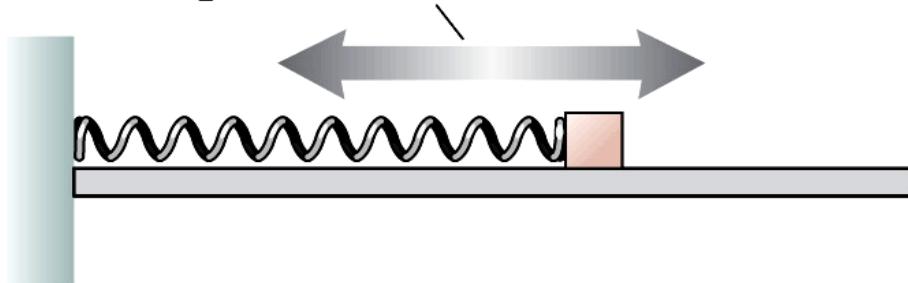

$$x = (5.00 \text{ cm}) \cos[(9.90 \text{ rad/s})t]$$

Example: A System in SHM

An air-track glider is attached to a spring, pulled 20 cm to the right, and released at $t=0$. It makes 15 complete oscillations in 10 s.

- What is the period of oscillation?
- What is the object's maximum speed?
- What is its position and velocity at $t=0.80$ s?

Simple harmonic motion of block

$$f = \frac{15 \text{ oscillations}}{10 \text{ s}} \\ = 1.5 \text{ oscillations/s} = 1.5 \text{ Hz}$$

$$T = 1/f = 0.667 \text{ s}$$

$$v_{\max} = \frac{2\pi A}{T} = \frac{2\pi(0.20 \text{ m})}{(0.667 \text{ s})} = 1.88 \text{ m/s}$$

$$x = A \cos \frac{2\pi t}{T} = (0.20 \text{ m}) \cos \frac{2\pi(0.80 \text{ s})}{(0.667 \text{ s})} = 0.062 \text{ m} = 6.2 \text{ cm}$$

$$v = -v_{\max} \sin \frac{2\pi t}{T} = -(1.88 \text{ m/s}) \sin \frac{2\pi(0.80 \text{ s})}{(0.667 \text{ s})} = -1.79 \text{ m/s}$$

Example: Finding the Time

A mass, oscillating in simple harmonic motion, starts at $x = A$ and has period T .

At what time, as a fraction of T , does the mass first pass through $x = \frac{1}{2}A$?

$$x = \frac{1}{2}A = A \cos \frac{2\pi t}{T}$$

$$t = \frac{T}{2\pi} \cos^{-1} \left(\frac{1}{2} \right) = \frac{T}{2\pi} \frac{\pi}{3} = \frac{1}{6}T$$

Ex. A particle execute s simple harmonic motion given by the equation

$$y = 12 \sin\left(\frac{2\pi t}{10} + \frac{\pi}{4}\right)$$

Calculate (i) amplitude, (ii) frequency, (iii) displacement at $t= 1.25s$, (iv) velocity at $t= 2.5s$ (v) acceleration at $t= 5s$.

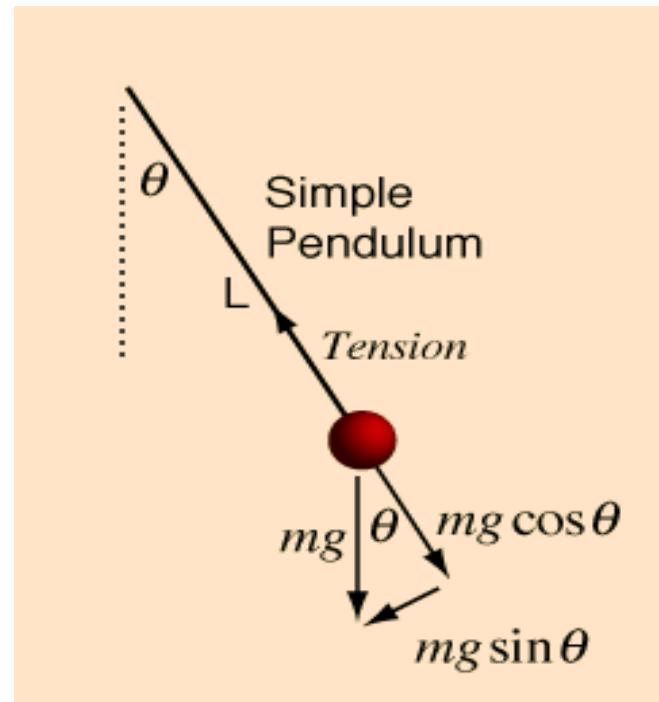

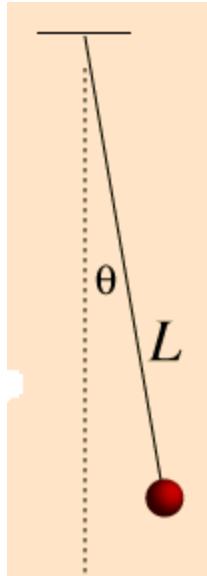

Ex. A particle execute s simple harmonic motion given by the equation

$$y = 10\sin(10t - \frac{\pi}{6})$$

Calculate (i) frequency, (ii) time period (iii) the maximum displacement (iv)the maximum velocity (v) the maximum acceleration acceleration.

Simple Pendulum

A *simple pendulum* consists of a particle of mass m , attached to a frictionless point by a cable of length L and negligible mass.

From the above figure restoring force

$$F = -mg \sin \theta$$

If the angle θ is very small $\sin \theta$ is very nearly equal to θ . The displacement along the arc is

$$x = L\theta$$

Therefore, $F = -mg\theta$

Acceleration $\frac{d^2x}{dt^2} = L \frac{d^2\theta}{dt^2}$

$$Force = mL \frac{d^2\theta}{dt^2}$$

$$mL \frac{d^2\theta}{dt^2} = -mg\theta$$

$$\frac{d^2\theta}{dt^2} + \frac{g}{L}\theta = 0$$

$$\frac{d^2x}{dt^2} + \omega^2 x = 0$$

Where

$$\omega^2 = \frac{g}{L}$$

And

$$T = 2\pi \sqrt{\frac{L}{g}}$$

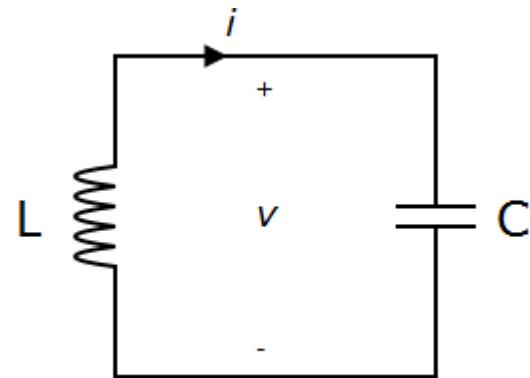

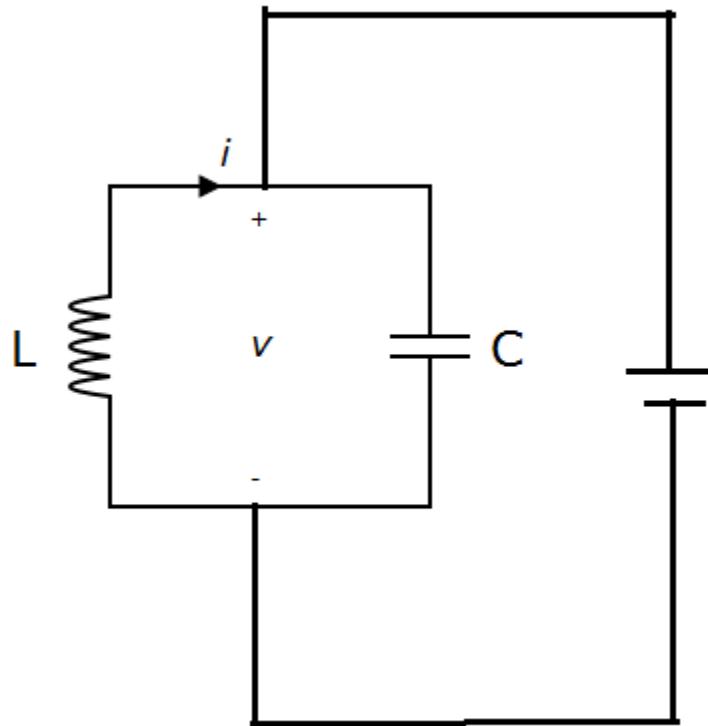

Example 10. Keeping Time

Determine the length of a simple pendulum that will swing back and forth in simple harmonic motion with a period of 1.00 s.

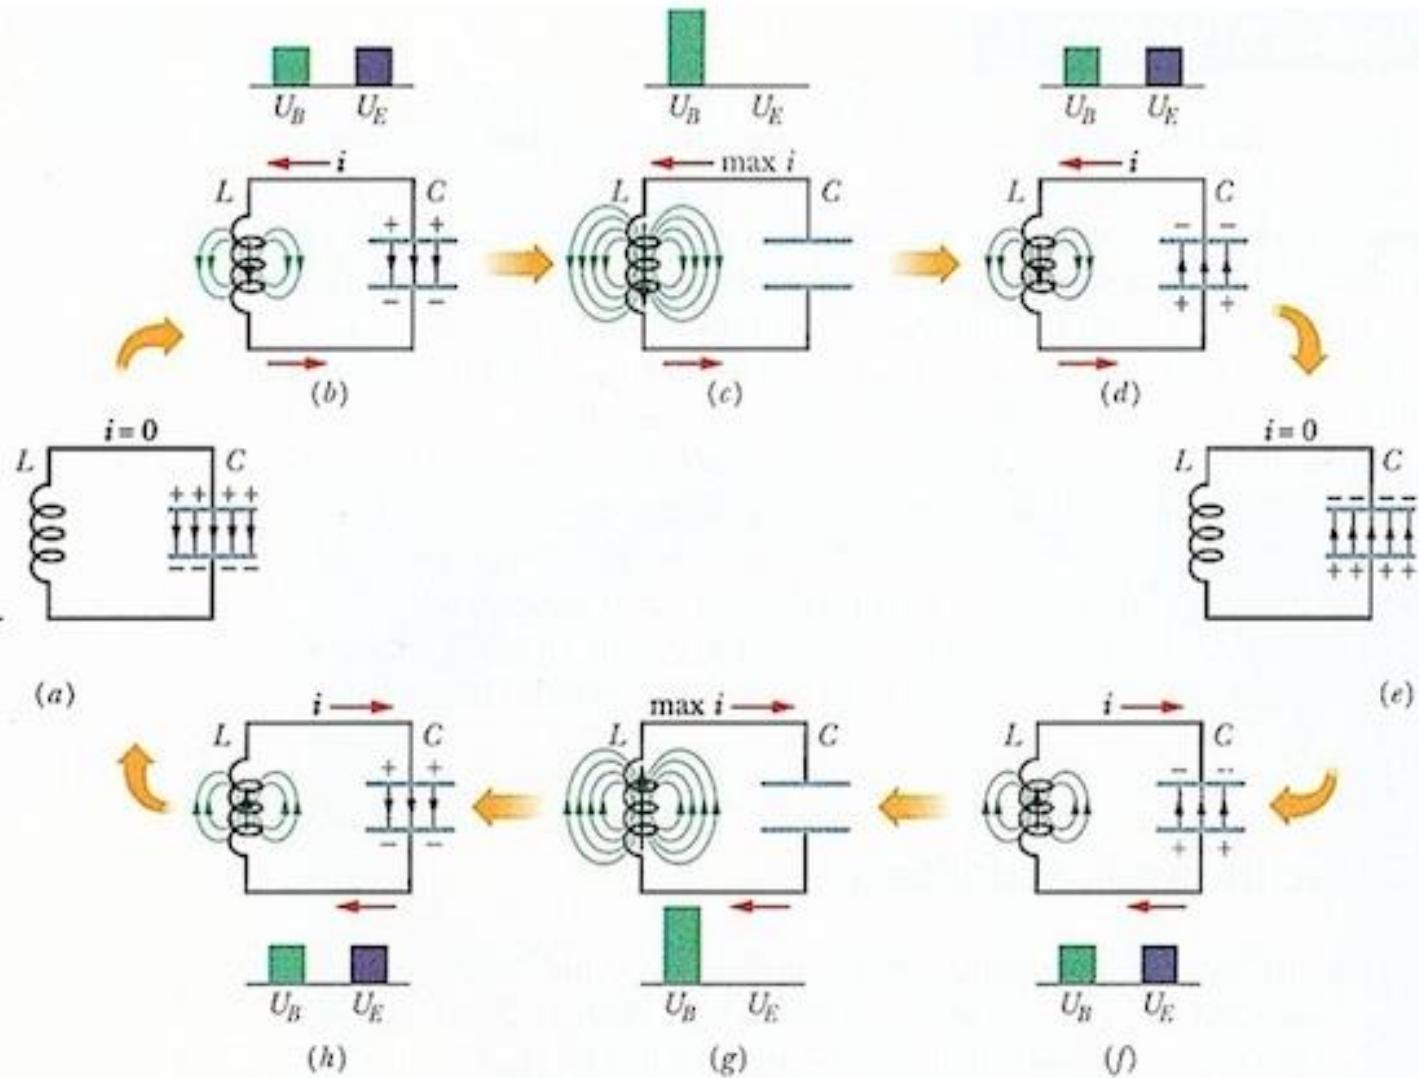

$$f = \frac{1}{2\pi} \sqrt{g / L}$$

$$L = \frac{T^2 g}{4\pi^2} = \frac{(1.00 \text{ s})^2 (9.80 \text{ m/s}^2)}{4\pi^2} = \boxed{0.248 \text{ m}}$$

LC Circuit

Charging discharging of an LC Circuit

An **LC circuit**, also called a **resonant circuit**, **tank circuit**, or **tuned circuit**, consists of an inductor, represented by the letter L, and a capacitor, represented by the letter C. When connected together, they can act as an electrical resonator.

Voltage across capacitor at any instant

$$V_C = \frac{Q}{C}$$

Q is the charge on the capacitor and C is capacitance of capacitor.

Voltage across inductor at the same instant

$$V_L = L \frac{di}{dt}$$

$$\frac{Q}{C} + L \frac{di}{dt} = 0 \quad \text{Kirchhoff's voltage law}$$

$$\frac{d^2i}{dt^2} + \frac{1}{LC} i = 0$$

Similar to differential equation of SHM

$$\frac{d^2x}{dt^2} + \omega_0^2 x = 0, \quad \omega_0^2 = \frac{1}{LC}$$

Time Period

$$T = 2\pi\sqrt{LC}$$

Frequency

$$f = \frac{1}{2\pi\sqrt{LC}}$$

Solution of the differential equation is

$$Q(t) = Q_0 \cos(\omega_0 t + \phi)$$

Current in the circuit

$$i(t) = -i_0 \sin(\omega_0 t + \phi)$$

Mechanical

displacement x

velocity v

mass m

spring constant k

$$\omega_0 = \sqrt{\frac{k}{m}}$$

potential energy: $\frac{1}{2}kx^2$

kinetic energy: $\frac{1}{2}mv^2$

Electrical

charge Q

current I

inductance L

$$\frac{1}{\text{capacitance}} \quad \frac{1}{C}$$

$$\omega_0 = \sqrt{\frac{1}{LC}}$$

Electric energy stored in capacitor: $\frac{1}{2}\frac{Q^2}{C}$

Magnetic energy stored in inductor: $\frac{1}{2}LI^2$

Damped oscillations

We have thus far neglected all dissipative mechanisms

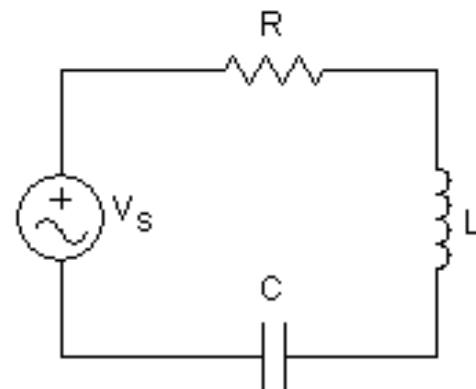

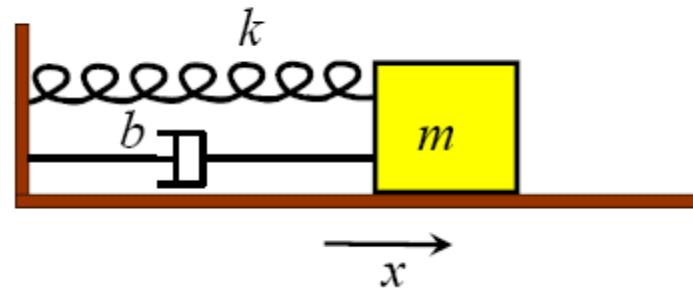

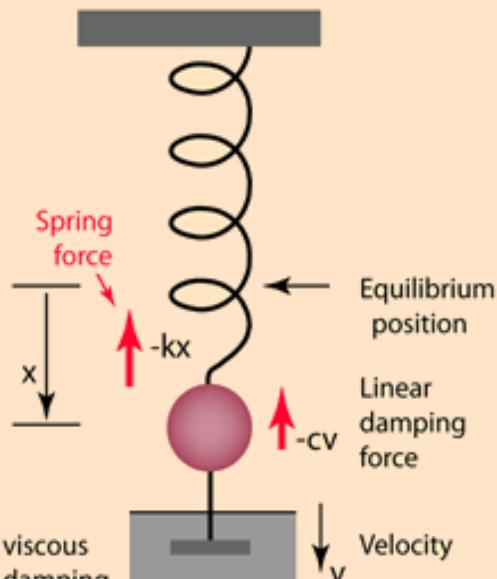

... our oscillations can continue oscillating with the same amplitude forever ...

Various physical damping mechanisms will contribute towards the damping...

- friction between mass and table
- “air resistance”
- internal friction in spring
-

... model these by introducing a damping force which is proportional to the velocity of the oscillator ...

Examples some damped oscillating systems

Damped Harmonic motion: When oscillating bodies do not move back and forth between precisely fixed limits because frictional force dissipate the energy and amplitude of oscillation decreases with time and finally die out. Such harmonic motion is called Damped Harmonic Motion.

Damped mass-spring system

In these systems the damping force

$$F' = -bv$$

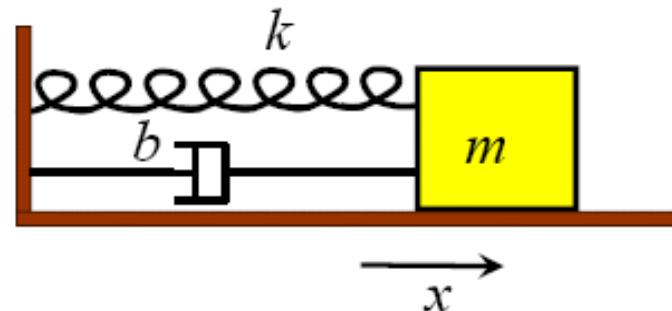

For horizontal forces on the mass: $ma = -kx - bv$

or $m \frac{d^2x}{dt^2} = -kx - b \frac{dx}{dt}$

or $\frac{d^2x}{dt^2} + \gamma \frac{dx}{dt} + \omega_0^2 x = 0$ where $\begin{cases} \omega_0 = \sqrt{\frac{k}{m}} \\ \gamma = \frac{b}{m} \end{cases}$

γ : "damping constant" unit: s^{-1}

• "life time" = $\frac{1}{\gamma}$

Damped oscillator equation

$$\frac{d^2x}{dt^2} + \gamma \frac{dx}{dt} + \omega_0^2 x = 0$$

Let $x = Be^{pt}$

Then $\frac{dx}{dt} = Bpe^{pt}$ and $\frac{d^2x}{dt^2} = Bp^2e^{pt}$

Substituting into DE: $Bp^2e^{pt} + \gamma Bpe^{pt} + \omega_0^2 Be^{pt} = 0$

Thus $p^2 + \gamma p + \omega_0^2 = 0$

$$\therefore p = \frac{1}{2} \left\{ -\gamma \pm \sqrt{\gamma^2 - 4\omega_0^2} \right\}$$

or $p = -\frac{\gamma}{2} \pm \sqrt{\frac{\gamma^2}{4} - \omega_0^2}$

$$ax^2 + bx + c = 0$$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

Damped oscillator equation ...2

$$p = -\frac{\gamma}{2} \pm \sqrt{\frac{\gamma^2}{4} - \omega_0^2}$$

We can distinguish three cases:

(i) $\omega_0^2 > \frac{\gamma^2}{4}$ **Oscillatory behaviour**

(ii) $\omega_0^2 = \frac{\gamma^2}{4}$ **Critical damping**

(iii) $\omega_0^2 < \frac{\gamma^2}{4}$ **Overdamping**

Case (i): $\omega_0^2 > \frac{\gamma^2}{4}$

$$\therefore \sqrt{\gamma^2/4 - \omega_0^2} = \sqrt{-(\omega_0^2 - \gamma^2/4)}$$

Put $\omega_1^2 = \omega_0^2 - \gamma^2/4$

$$\therefore p = -\frac{\gamma}{2} \pm \sqrt{-\omega_1^2} = -\frac{\gamma}{2} \pm j\omega_1$$

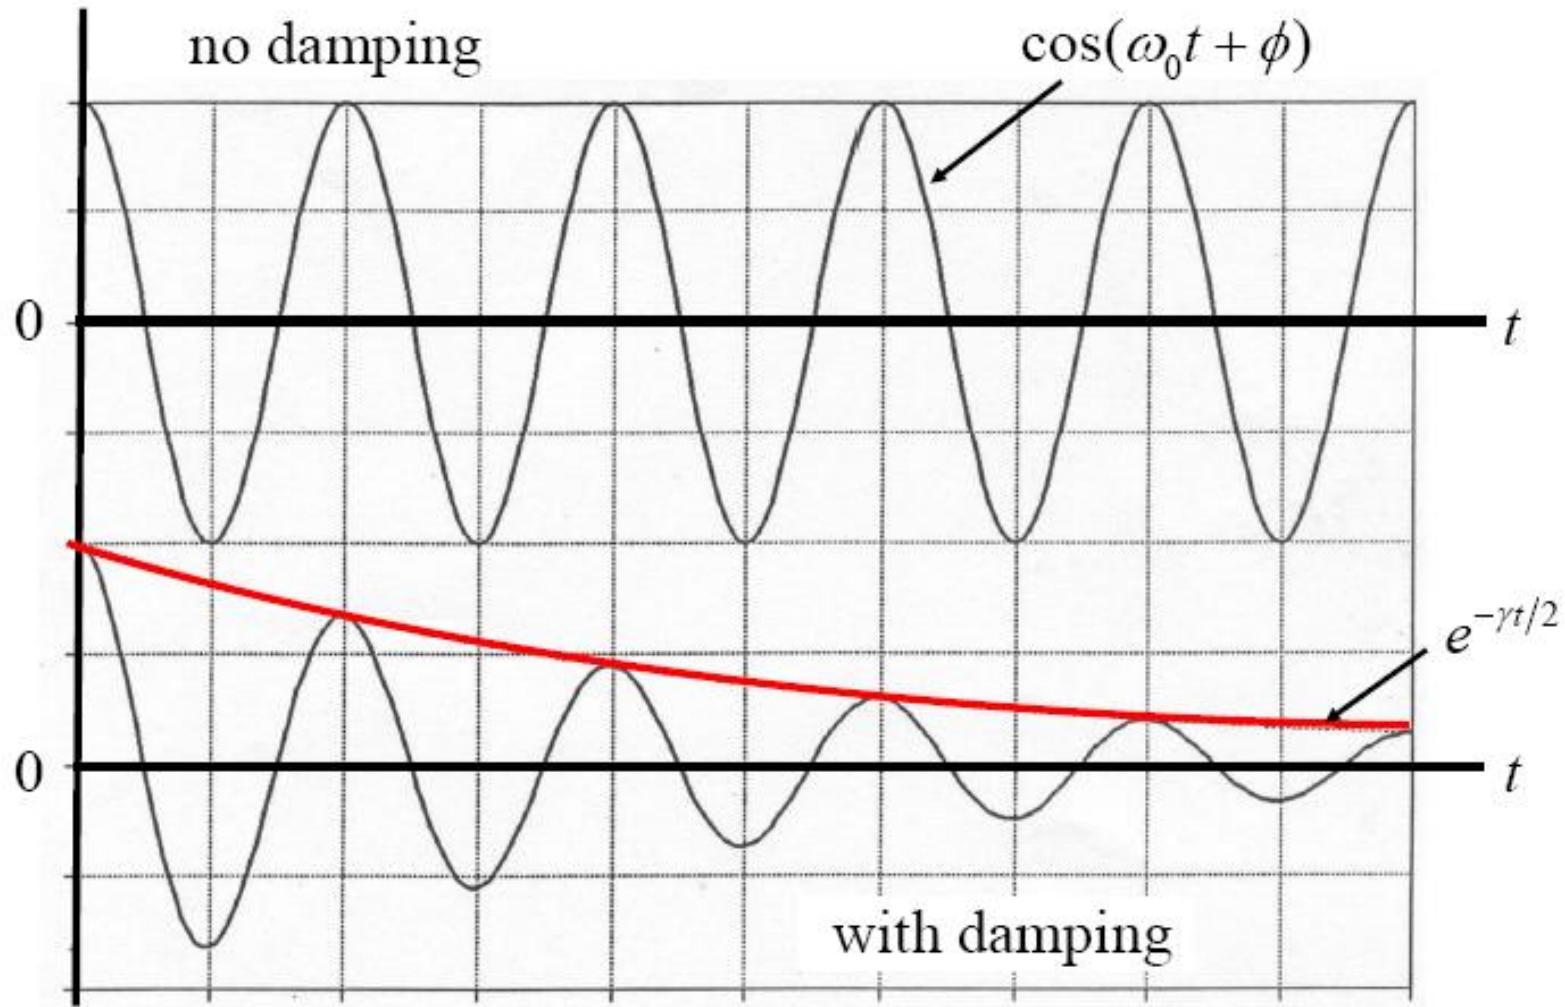

The solution will be:

$$x = B_1 e^{(\frac{\gamma}{2} + j\omega_1)t} + B_2 e^{(\frac{\gamma}{2} - j\omega_1)t} = e^{-\frac{\gamma}{2}t} \left\{ B_1 e^{j\omega_1 t} + B_2 e^{-j\omega_1 t} \right\}$$

... leading to $x(t) = A e^{-\frac{\gamma t}{2}} \cos(\omega_1 t + \phi)$

This is an **oscillatory solution** $A \cos(\omega_1 t + \phi)$ multiplied by a damping factor $e^{-\gamma t/2}$.

As $\gamma \rightarrow 0$ we approach our undamped oscillator.

Case (ii): $\omega_0^2 = \frac{\gamma^2}{4}$

The two roots coincide: $p = -\frac{\gamma}{2}$

The solution will be $x(t) = (A + Bt)e^{-\frac{\gamma}{2}t}$

The condition $\omega_0^2 = \gamma^2/4$ is referred to as the
“critical damping” condition.

If $\omega_0^2 < \gamma^2/4$ a system released from rest will oscillate.

As γ is increased the oscillations decay more rapidly, until
at $\omega_0^2 = \gamma^2/4$ oscillation no longer occurs.

[... many practical applications ...]

Case (iii): $\omega_0^2 < \frac{\gamma^2}{4}$

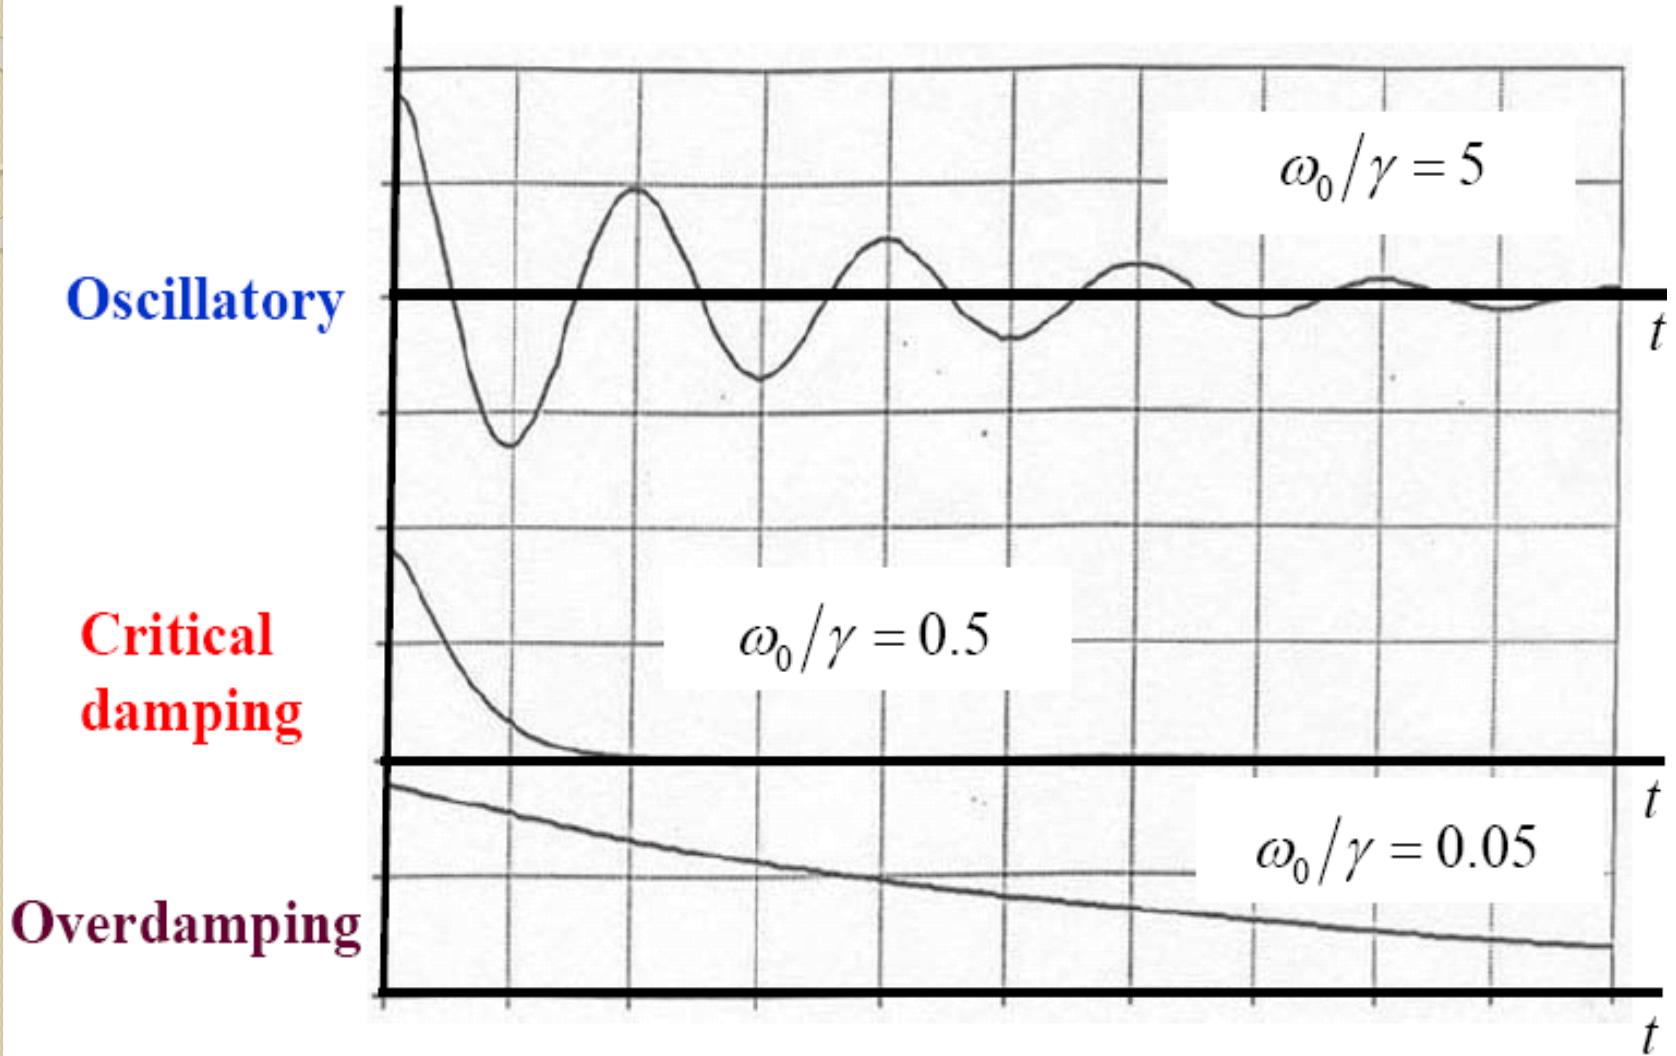

$$p = -\frac{\gamma}{2} \pm \sqrt{\frac{\gamma^2}{4} - \omega_0^2}$$

$$= -\frac{\gamma}{2} \pm \lambda \quad \text{say}$$

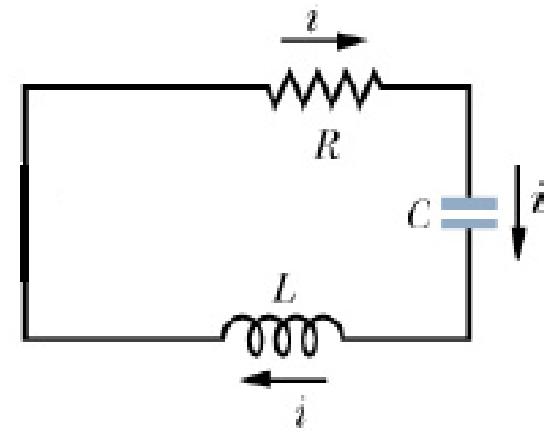

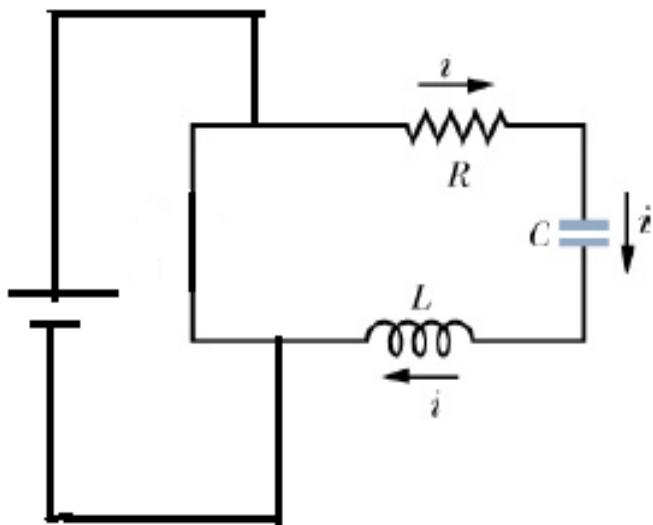

The solution will be $x(t) = B_1 e^{(-\frac{\gamma}{2} + \lambda)t} + B_2 e^{(-\frac{\gamma}{2} - \lambda)t}$

The condition $\omega_0^2 < \frac{\gamma^2}{4}$ is referred to as **overdamping**

... a slower approach to the rest position is observed.

RLC circuit

- Voltage across resistor R $V_R = iR$
- Voltage across capacitor C $V_C = \frac{Q}{C}$
- Voltage across inductor L $V_L = L \frac{di}{dt}$
- According to Kirchhoff's voltage law

$$iR + \frac{Q}{C} + L \frac{di}{dt} = 0$$

Rewrite the equation

$$\frac{d^2i}{dt^2} + \frac{R}{L} \frac{di}{dt} + \frac{1}{LC} i = 0$$

Comparing with the equation

$$\frac{d^2x}{dt^2} + \gamma \frac{dx}{dt} + \omega_0^2 x = 0$$

Where

$$\gamma = \frac{R}{L} \quad \omega_0 = \sqrt{\frac{1}{LC}}$$

Three distinguish cases are

i) $\frac{1}{LC} > \frac{R^2}{4L^2}$ **Oscillatory behavior**

ii) $\frac{1}{LC} = \frac{R^2}{4L^2}$ **Critical damping**

iii) $\frac{1}{LC} < \frac{R^2}{4L^2}$ **Over damping**

Case i) $\frac{1}{LC} > \frac{R^2}{4L^2}$

Solution of the differential equation

$$Q(t) = Ae^{-\frac{R}{2L}t} \cos(\omega_1 t + \phi)$$

Where $\omega_1 = \sqrt{\left(\frac{1}{LC} - \frac{R^2}{4L^2}\right)}$

Frequency of oscillation

$$f = \frac{1}{2\pi} \sqrt{\left(\frac{1}{LC} - \frac{R^2}{4L^2}\right)}$$

EX. A capacitor $1.0\mu\text{F}$, an inductor 0.2H and a resistance 800Ω are joined in series. Is the circuit oscillatory? Find the frequency of oscillation.

Ex. Find whether the discharge of capacitor through the following inductive circuit is oscillatory.
 $C = 0.1\mu\text{F}$, $L = 10\text{mh}$, $R = 200 \Omega$
If Oscillatory, find the frequency of oscillation.

Review: Simple Harmonic Motion

- The position x of an object moving in simple harmonic motion as a function of time has the following form:

$$x = A \cos(\omega t + \phi)$$

i.e. the object periodically moves back and forth between the amplitudes $x=+A$ and $x=-A$.

The time it takes for the object to make one full cycle is the period $T=2\pi/\omega=1/f$, where f is the frequency of the motion.

Thus, the angular speed in terms of T and f reads

$$\omega = 2\pi/T \quad \text{and} \quad \omega = 2\pi f$$

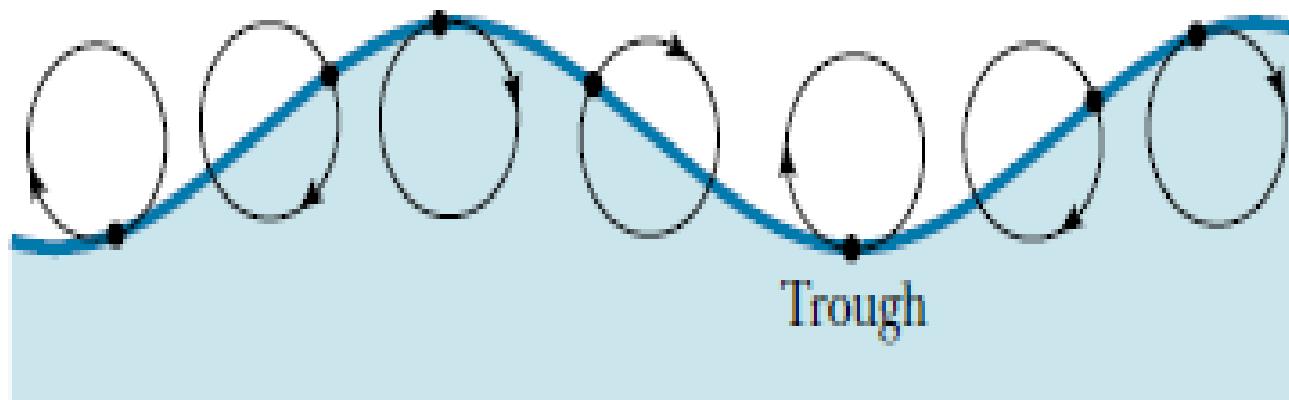

What is a wave ?

- Nature of waves:
 - A wave is a traveling disturbance that transports energy from place to place.
 - There are two basic types of waves: transverse and longitudinal.
 - Transverse: the disturbance travels perpendicular to the direction of travel of the wave.
 - Longitudinal: the disturbance occurs parallel to the line of travel of the wave.

Wave motion 

Crest

Trough

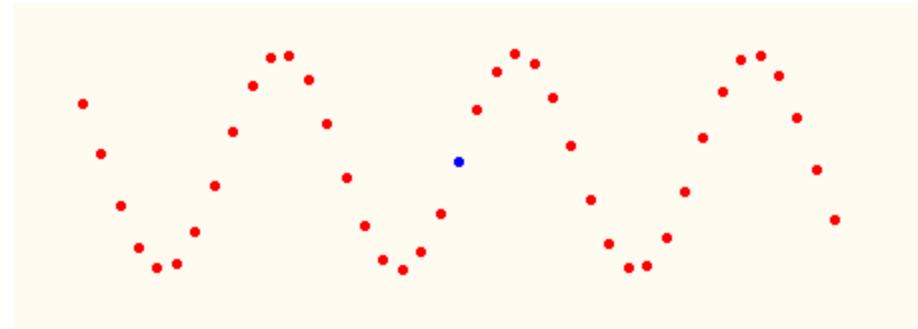

- Examples:
 - **Longitudinal:** Sound waves (e.g. air moves back & forth)
 - **Transverse:** Light waves (electromagnetic waves, i.e. electric and magnetic disturbances)

The source of the wave, i.e. the disturbance, moves continuously in simple harmonic motion, generating an entire wave, where each part of the wave also performs a simple harmonic motion.

Types of Waves

- **Transverse:** The medium oscillates perpendicular to the direction the wave is moving.

- Water waves

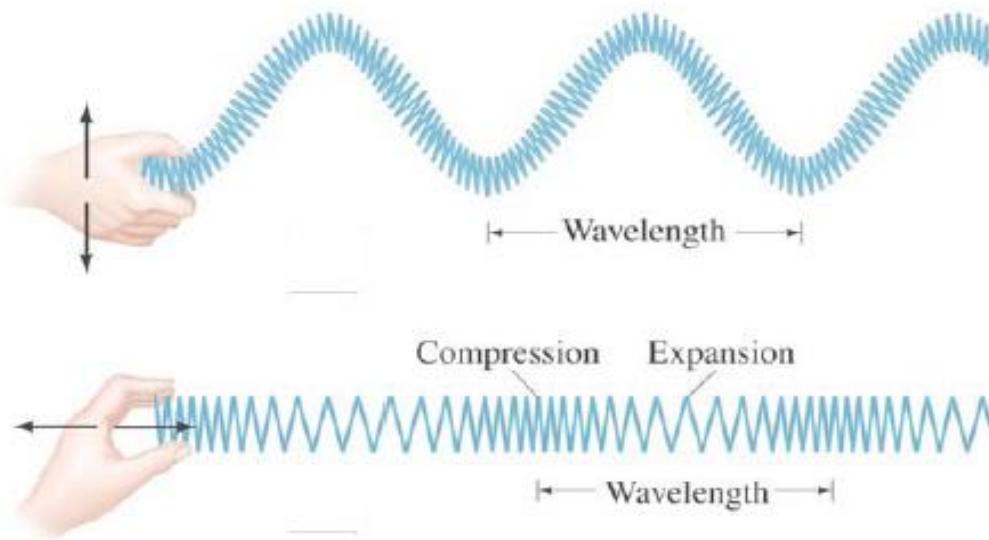

- **Longitudinal:** The medium oscillates in the same direction as the wave is moving

- Sound

Types of Waves: Transverse and Longitudinal

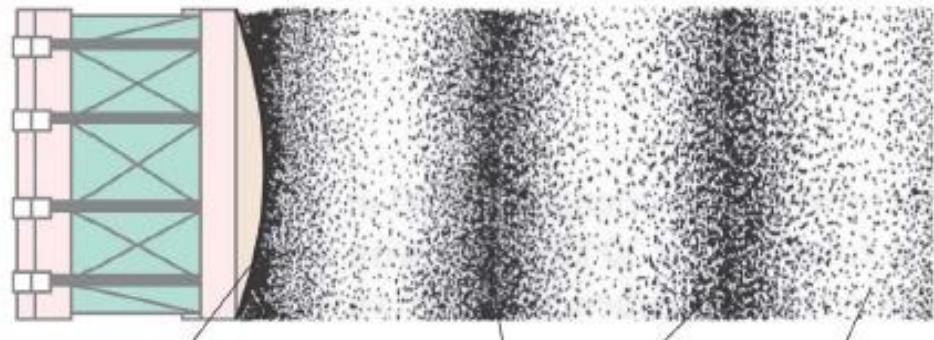

The motion of particles in a wave can be either perpendicular to the wave direction (transverse) or parallel to it (longitudinal).

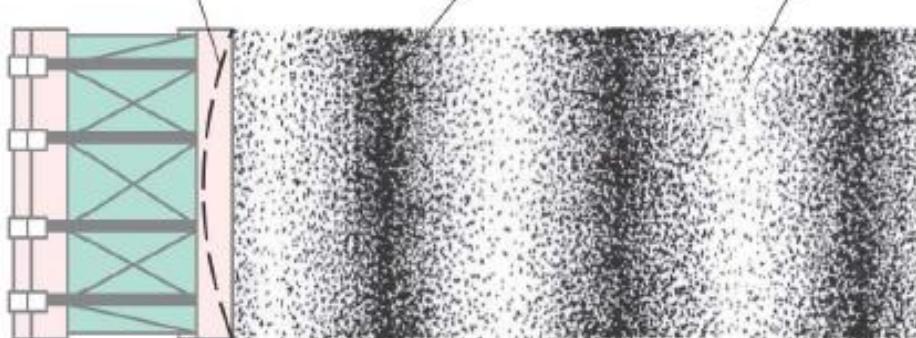

Types of Waves: Transverse and Longitudinal

Sound waves are longitudinal waves:

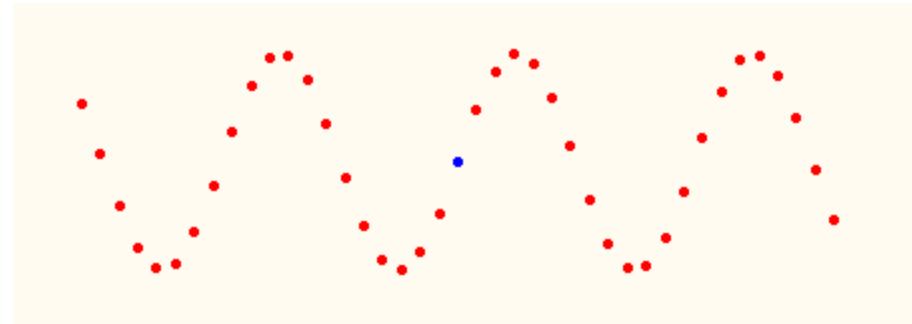

Drum membrane Compression Expansion

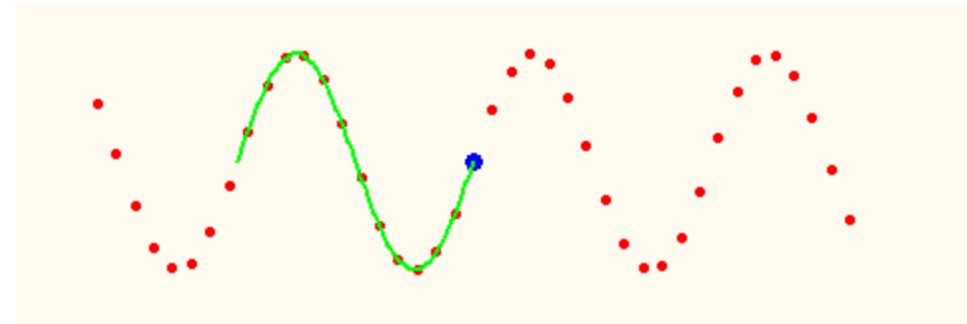

Wave Properties...

- Period: The time T for a point on the wave to undergo one complete oscillation.

- Speed: The wave moves one wavelength λ in one period T so its speed is $v = \lambda / T$.

$$v = \frac{\lambda}{T}$$

Wave Properties...

- The speed of a wave is a constant that depends only on the medium, not on the amplitude, wavelength or period:
 λ and T are related !

→ $\lambda = v T$ or $\lambda = 2\pi v / \omega$ (since $T = 2\pi / \omega$)

or $\lambda = v / f$ (since $T = 1/f$)

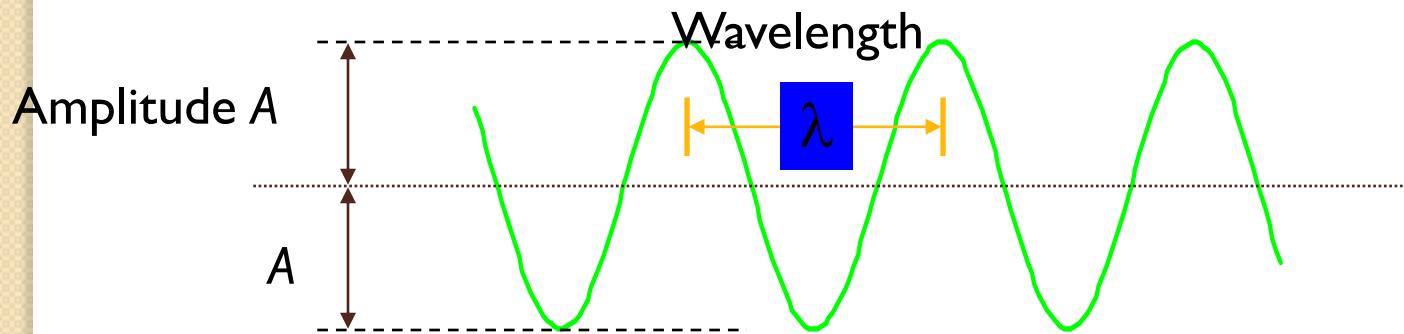

- Recall $f = \text{cycles/sec}$ or revolutions/sec
 $\omega = 2\pi f$

Is the speed of a wave particle the same as the speed of the wave ?

No. Wave particle performs simple harmonic motion: $v = A \omega \sin \omega t$.

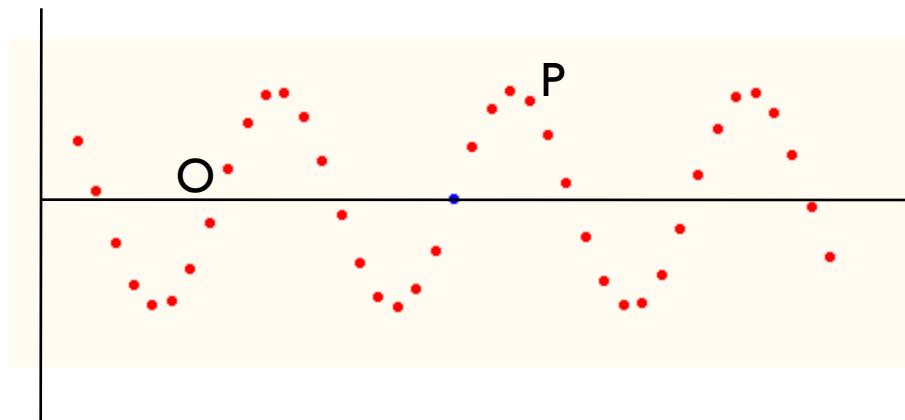

Wave Properties

- Amplitude: The maximum displacement A of a point on the wave.
- Wavelength: The distance λ between identical points on the wave.

Equation for a Progressive Wave

The simplest type of wave is the one in which the particles of the medium are set into simple harmonic vibrations as the wave passes through it. The wave is then called a simple harmonic wave.

Consider a particle O in the medium.
The displacement at any instant of time is
given by

$$y = A \sin \omega t \dots\dots\dots (I)$$

Where A is the amplitude, ω is the angular frequency of the wave. Consider a particle P at a distance x from the particle O on its right. Let the wave travel with a velocity v from left to right. Since it takes some time for the disturbance to reach P, its displacement can be written as

$$y = A \sin (\omega t - \phi) \dots \dots \dots (2)$$

Where ϕ is the phase difference between the particles O and P.

We know that a path difference of λ corresponds to a phase difference of 2π radians. Hence a path difference of x corresponds to a phase difference of

$$\frac{2\pi}{\lambda} \cdot x$$

$$\phi = \frac{2\pi x}{\lambda}$$

Displacement of particle P is

$$y = A \sin(\omega t - \frac{2\pi x}{\lambda}) \dots\dots\dots(3)$$

But $\omega = \frac{2\pi}{T}$

$$y = A \sin\left(\frac{2\pi t}{T} - \frac{2\pi x}{\lambda}\right) \dots\dots\dots(5)$$

$$y = A \sin 2\pi \left(\frac{t}{T} - \frac{x}{\lambda} \right)$$

But $v = \frac{\lambda}{T}$ or $T = \frac{\lambda}{v}$

$$y = A \sin 2\pi \left(\frac{vt}{\lambda} - \frac{x}{\lambda} \right)$$

$$y = A \sin \frac{2\pi}{\lambda} (vt - x) \dots \dots \dots (6)$$

Similarly, for a particle at a distance x to the left of 0, the equation for the displacement is given by

$$y = A \sin \frac{2\pi}{\lambda} (vt + x) \dots \dots \dots \quad (7)$$

Differential equation for wave motion

We have wave equation

$$y = A \sin \frac{2\pi}{\lambda} (vt - x) \dots\dots\dots(1)$$

Differentiating equation with respect to x,
We get,

$$\frac{dy}{dx} = A \frac{2\pi}{\lambda} \cos \frac{2\pi}{\lambda} (vt - x) \dots\dots\dots(2)$$

$\frac{dy}{dx}$ represents the strain or the compression. When $\frac{dy}{dx}$ is positive, a rarefaction takes place and when $\frac{dy}{dx}$ is negative, a compression takes place.

The velocity of the particle whose displacement y is represented by equation, is obtained by differentiating it with respect to t , since velocity is the rate of change of displacement with respect to time.

$$\frac{dy}{dt} = A \frac{2\pi v}{\lambda} \cos \frac{2\pi}{\lambda} (vt - x) \dots\dots\dots(3)$$

Comparing equations (2) and (3) we get,

$$\frac{dy}{dt} = v \frac{dy}{dx} \dots\dots\dots(4)$$

Particle velocity = wave velocity x slope of the displacement curve or strain.

Differentiating equation (2)

$$\frac{d^2y}{dx^2} = -A \frac{4\pi^2}{\lambda^2} \sin \frac{2\pi}{\lambda} (vt - x) \dots\dots\dots(5)$$

Differentiating equation (3)

$$\frac{d^2y}{dt^2} = -A \frac{4\pi^2 v^2}{\lambda^2} \sin \frac{2\pi}{\lambda} (vt - x) \dots\dots\dots(6)$$

Comparing equs. (5) and (6)

$$\frac{d^2y}{dt^2} = v^2 \frac{d^2y}{dx^2} \dots\dots\dots(7)$$

Equation (7) represents the differential equation of wave velocity

Ex. The equation of a traveling wave is

$$y = 4.0 \sin \pi(0.10x - 2t)$$

Find (i) wavelength, (ii) speed and
(iii) frequency of oscillating particle of the
wave

Ex. When a simple harmonic wave is propagated through a medium, the displacement of a particle in cm at any instant is

$$y = 10 \sin \frac{2\pi}{100} (3600t - 20)$$

Calculate the amplitude, wave velocity, wavelength, frequency and period of the oscillating particle.

- Ex. The equation of a traveling wave is

$$y = 4.0 \sin \pi(0.10x - 2t)$$

Find (i) amplitude (ii) wavelength (iii) speed
(iv) frequency of wave

When a simple harmonic wave is propagated through a medium, the displacement of the particle at any instant of time is given by

$$y = 5.0 \sin \pi(360t - 0.15x)$$

calculate

- (i)the amplitude of the vibrating particle,
- (ii)wave velocity,
- (ii)wave length,
- (iv)frequency and
- (v) time period.

Ex.A simple harmonic wave of amplitude 8units travels a line of particles in the direction of positive X axis. At any instant for a particle at a distance of 10cm from the origin, the displacement is +6units and at a distance a particle from the origin is 25units, the displacement is +4units. Calculate the wavelength.

When two waves overlap, we see the resultant wave, not the individual waves.

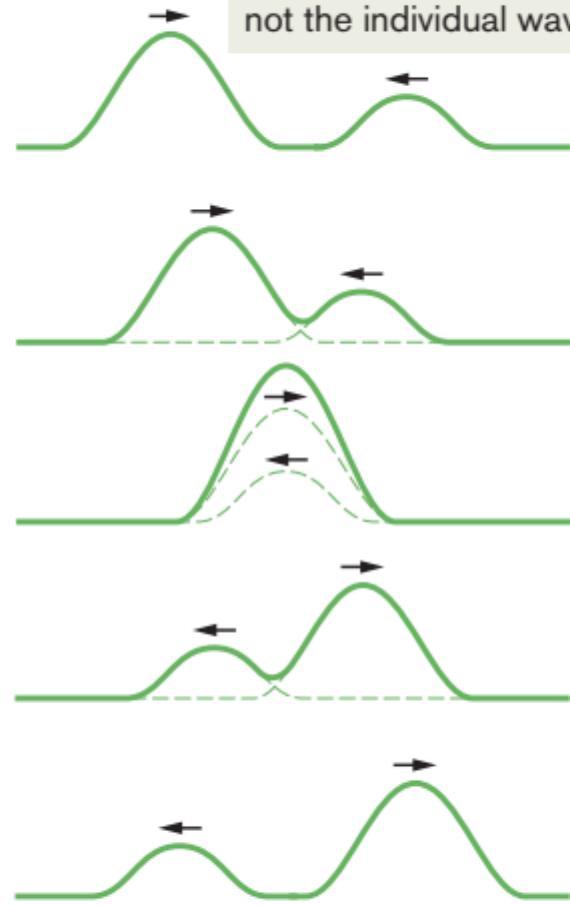

Figure 16-12 A series of snapshots that show two pulses traveling in opposite directions along a stretched string. The superposition principle applies as the pulses move through each other.

The Principle of Superposition for Waves

It often happens that two or more waves pass simultaneously through a region. When we listen to a concert, for example, sound waves from many instruments fall simultaneously on our eardrums. The electrons in the antenna of a radio and television receiver are set in motion by the net effect of many magnetic waves from many different broadcasting centers. The water of a harbor may be churned up by waves in the wakes of many boats.

Suppose that two waves travel simultaneously along the same string. Let $y_1(x, t)$ and $y_2(x, t)$ be the displacements that the string would experience if each wave traveled alone. The displacement of the string when the two waves overlap is then the algebraic sum

$$y'(x, t) = y_1(x, t) + y_2(x, t).$$

This summation of displacements along the string means that

Overlapping waves algebraically add to produce a **resultant wave** (or **net wave**).

This is another example of the **principle of superposition**, which says that if several effects occur simultaneously, their net effect is the sum of the individual effects. (We should be thankful that only a simple sum is needed. If two waves somehow amplified each other, the resulting nonlinear world would be very difficult to manage and understand.)

Figure 16-12 shows a sequence of snapshots of two pulses traveling in opposite directions on the same stretched string. When the pulses overlap, the resultant pulse is their sum. Moreover,

Overlapping waves do not in any way alter the travel of each other.

Interference of Waves

Suppose we send two sinusoidal waves of the same wavelength and amplitude in the same direction along a stretched string. The superposition principle applies. What resultant wave does it predict for the string?

The resultant wave depends on the extent to which the waves are *in phase* (in step) with respect to each other—that is, how much one wave form is shifted from the other wave form. If the waves are exactly in phase (so that the peaks and valleys of one are exactly aligned with those of the other), they combine to double the displacement of either wave acting alone. If they are exactly out of phase (the peaks of one are exactly aligned with the valleys of the other), they combine to cancel everywhere, and the string remains straight. We call this phenomenon of combining waves **interference**, and the waves are said to **interfere**. (These terms refer only to the wave displacements; the travel of the waves is unaffected.)

Let one wave traveling along a stretched string be given by

$$y_1(x, t) = y_m \sin(kx - \omega t) \quad (16-47)$$

and another, shifted from the first, by

$$y_2(x, t) = y_m \sin(kx - \omega t + \phi). \quad (16-48)$$

From the principle of superposition (Eq. 16-46), the resultant wave is the algebraic sum of the two interfering waves and has displacement

$$\begin{aligned}y'(x, t) &= y_1(x, t) + y_2(x, t) \\&= y_m \sin(kx - \omega t) + y_m \sin(kx - \omega t + \phi).\end{aligned}\quad (16-49)$$

In Appendix E we see that we can write the sum of the sines of two angles α and β as

$$\sin \alpha + \sin \beta = 2 \sin \frac{1}{2}(\alpha + \beta) \cos \frac{1}{2}(\alpha - \beta).\quad (16-50)$$

Applying this relation to Eq. 16-49 leads to

$$y'(x, t) = [2y_m \cos \frac{1}{2}\phi] \sin(kx - \omega t + \frac{1}{2}\phi).\quad (16-51)$$

As Fig. 16-13 shows, the resultant wave is also a sinusoidal wave traveling in the direction of increasing x . It is the only wave you would actually see on the string (you would *not* see the two interfering waves of Eqs. 16-47 and 16-48).

If two sinusoidal waves of the same amplitude and wavelength travel in the *same* direction along a stretched string, they interfere to produce a resultant sinusoidal wave traveling in that direction.

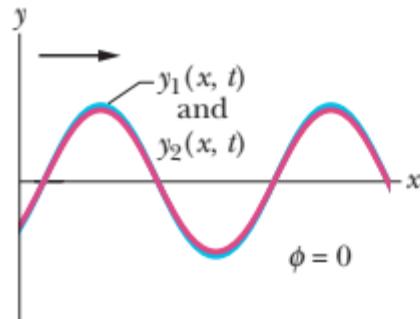

The resultant wave differs from the interfering waves in two respects: (1) its phase constant is $\frac{1}{2}\phi$, and (2) its amplitude y'_m is the magnitude of the quantity in the brackets in Eq. 16-51:

$$y'_m = |2y_m \cos \frac{1}{2}\phi| \quad (\text{amplitude}).\quad (16-52)$$

If $\phi = 0$ rad (or 0°), the two interfering waves are exactly in phase and Eq. 16-51 reduces to

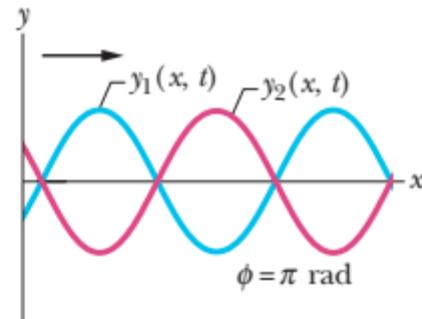

$$y'(x, t) = 2y_m \sin(kx - \omega t) \quad (\phi = 0).\quad (16-53)$$

Being exactly in phase,
the waves produce a
large resultant wave.

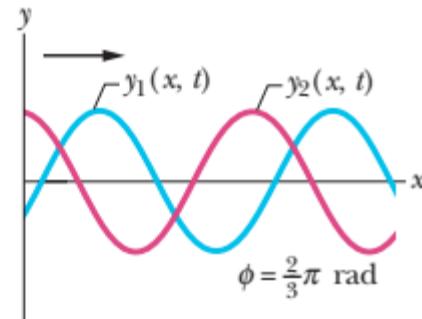

(a)

Being exactly out of
phase, they produce
a flat string.

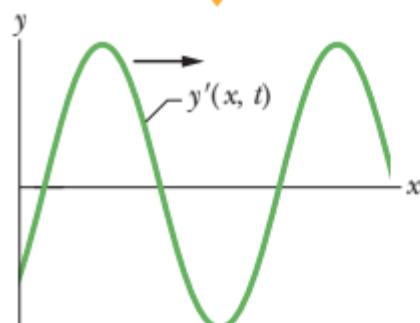

(b)

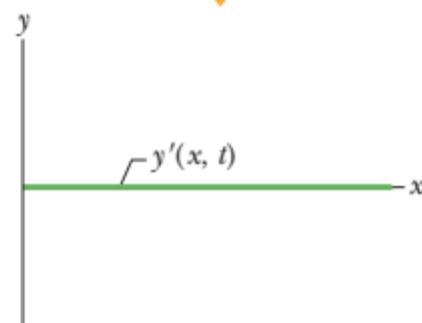

This is an intermediate
situation, with an
intermediate result.

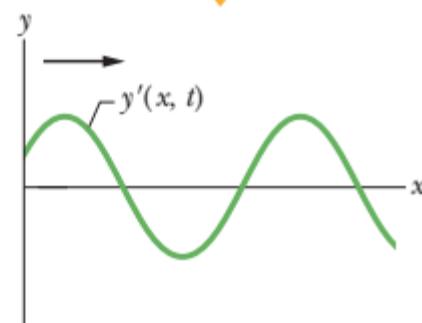

(c)

(d)

(e)

(f)

Because a sinusoidal wave repeats its shape every 2π rad, a phase difference of $\phi = 2\pi$ rad (or 360°) corresponds to a shift of one wave relative to the other wave by a distance equivalent to one wavelength. Thus, phase differences can be described in terms of wavelengths as well as angles. For example, in Fig. 16-14b the waves may be said to be 0.50 wavelength out of phase. Table 16-1 shows some other examples of phase differences and the interference they produce. Note that when interference is neither fully constructive nor fully destructive, it is called *intermediate interference*. The amplitude of the resultant wave is then intermediate between 0 and $2y_m$. For example, from Table 16-1, if the interfering waves have a phase difference of 120° ($\phi = \frac{2}{3}\pi$ rad = 0.33 wavelength), then the resultant wave has an amplitude of y_m , the same as that of the interfering waves (see Figs. 16-14c and f).

Table 16-1 Phase Difference and Resulting Interference Types^a

Phase Difference, in			Amplitude of Resultant Wave	Type of Interference
Degrees	Radians	Wavelengths		
0	0	0	$2y_m$	Fully constructive
120	$\frac{2}{3}\pi$	0.33	y_m	Intermediate
180	π	0.50	0	Fully destructive
240	$\frac{4}{3}\pi$	0.67	y_m	Intermediate
360	2π	1.00	$2y_m$	Fully constructive
865	15.1	2.40	$0.60y_m$	Intermediate

Two identical sinusoidal waves, moving in the same direction along a stretched string, interfere with each other. The amplitude y_m of each wave is 9.8 mm, and the phase difference ϕ between them is 100° .

- (a) What is the amplitude y'_m of the resultant wave due to the interference, and what is the type of this interference?

Calculations: Because they are identical, the waves have the *same amplitude*. Thus, the amplitude y'_m of the resultant wave is given by Eq. 16-52:

$$\begin{aligned}y'_m &= |2y_m \cos \frac{1}{2}\phi| = |(2)(9.8 \text{ mm}) \cos(100^\circ/2)| \\&= 13 \text{ mm.} \quad (\text{Answer})\end{aligned}$$

We can tell that the interference is *intermediate* in two ways. The phase difference is between 0 and 180° , and, correspondingly, the amplitude y'_m is between 0 and $2y_m$ ($= 19.6 \text{ mm}$).

(b) What phase difference, in radians and wavelengths, will give the resultant wave an amplitude of 4.9 mm?

Calculations: Now we are given y'_m and seek ϕ . From Eq. 16-52,

$$y'_m = |2y_m \cos \frac{1}{2}\phi|,$$

we now have

$$4.9 \text{ mm} = (2)(9.8 \text{ mm}) \cos \frac{1}{2}\phi,$$

which gives us (with a calculator in the radian mode)

$$\begin{aligned}\phi &= 2 \cos^{-1} \frac{4.9 \text{ mm}}{(2)(9.8 \text{ mm})} \\ &= \pm 2.636 \text{ rad} \approx \pm 2.6 \text{ rad.} \quad (\text{Answer})\end{aligned}$$

There are two solutions because we can obtain the same resultant wave by letting the first wave *lead* (travel ahead of) or *lag* (travel behind) the second wave by 2.6 rad. In wavelengths, the phase difference is

$$\begin{aligned}\frac{\phi}{2\pi \text{ rad/wavelength}} &= \frac{\pm 2.636 \text{ rad}}{2\pi \text{ rad/wavelength}} \\ &= \pm 0.42 \text{ wavelength.} \quad (\text{Answer})\end{aligned}$$

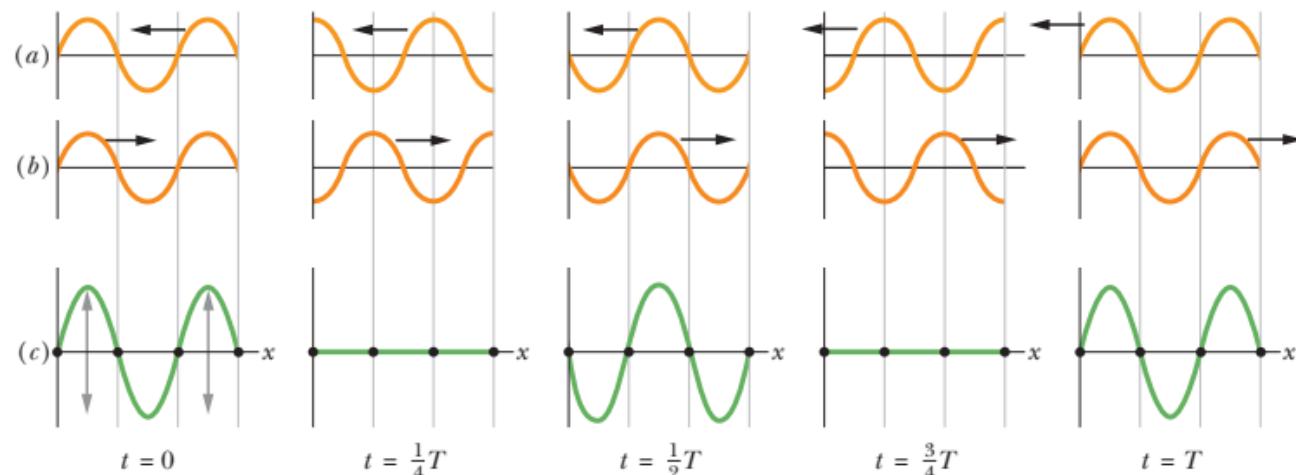

Standing Waves

In Module 16-5, we discussed two sinusoidal waves of the same wavelength and amplitude traveling *in the same direction* along a stretched string. What if they travel in opposite directions? We can again find the resultant wave by applying the superposition principle.

Figure 16-17 suggests the situation graphically. It shows the two combining waves, one traveling to the left in Fig. 16-17a, the other to the right in Fig. 16-17b. Figure 16-17c shows their sum, obtained by applying the superposition

Figure 16-17 (a) Five snapshots of a wave traveling to the left, at the times t indicated below part (c) (T is the period of oscillation). (b) Five snapshots of a wave identical to that in (a) but traveling to the right, at the same times t . (c) Corresponding snapshots for the superposition of the two waves on the same string. At $t = 0, \frac{1}{2}T$, and T , fully constructive interference occurs because of the alignment of peaks with peaks and valleys with valleys. At $t = \frac{1}{4}T$ and $\frac{3}{4}T$, fully destructive interference occurs because of the alignment of peaks with valleys. Some points (the nodes, marked with dots) never oscillate; some points (the antinodes) oscillate the most.

As the waves move through each other, some points never move and some move the most.

If two sinusoidal waves of the same amplitude and wavelength travel in *opposite* directions along a stretched string, their interference with each other produces a standing wave.

To analyze a standing wave, we represent the two waves with the equations

$$y_1(x, t) = y_m \sin(kx - \omega t) \quad (16-58)$$

and

$$y_2(x, t) = y_m \sin(kx + \omega t). \quad (16-59)$$

The principle of superposition gives, for the combined wave,

$$y'(x, t) = y_1(x, t) + y_2(x, t) = y_m \sin(kx - \omega t) + y_m \sin(kx + \omega t).$$

Applying the trigonometric relation of Eq. 16-50 leads to Fig. 16-18 and

$$y'(x, t) = [2y_m \sin kx] \cos \omega t. \quad (16-60)$$

The quantity $2y_m \sin kx$ in the brackets of Eq. 16-60 can be viewed as the amplitude of oscillation of the string element that is located at position x . However, since an amplitude is always positive and $\sin kx$ can be negative, we take the absolute value of the quantity $2y_m \sin kx$ to be the amplitude at x .

In a traveling sinusoidal wave, the amplitude of the wave is the same for all string elements. That is not true for a standing wave, in which the amplitude *varies with position*. In the standing wave of Eq. 16-60, for example, the amplitude is zero for values of kx that give $\sin kx = 0$. Those values are

$$kx = n\pi, \quad \text{for } n = 0, 1, 2, \dots \quad (16-61)$$

Substituting $k = 2\pi/\lambda$ in this equation and rearranging, we get

$$x = n \frac{\lambda}{2}, \quad \text{for } n = 0, 1, 2, \dots \quad (\text{nodes}), \quad (16-62)$$

as the positions of zero amplitude—the nodes—for the standing wave of Eq. 16-60. Note that adjacent nodes are separated by $\lambda/2$, half a wavelength.

The amplitude of the standing wave of Eq. 16-60 has a maximum value of $2y_m$, which occurs for values of kx that give $|\sin kx| = 1$. Those values are

$$\begin{aligned} kx &= \frac{1}{2}\pi, \frac{3}{2}\pi, \frac{5}{2}\pi, \dots \\ &= (n + \frac{1}{2})\pi, \quad \text{for } n = 0, 1, 2, \dots \end{aligned} \quad (16-63)$$

Substituting $k = 2\pi/\lambda$ in Eq. 16-63 and rearranging, we get

$$x = \left(n + \frac{1}{2}\right) \frac{\lambda}{2}, \quad \text{for } n = 0, 1, 2, \dots \quad (\text{antinodes}), \quad (16-64)$$

as the positions of maximum amplitude—the antinodes—of the standing wave of Eq. 16-60. Antinodes are separated by $\lambda/2$ and are halfway between nodes.

Introduction to stationary waves

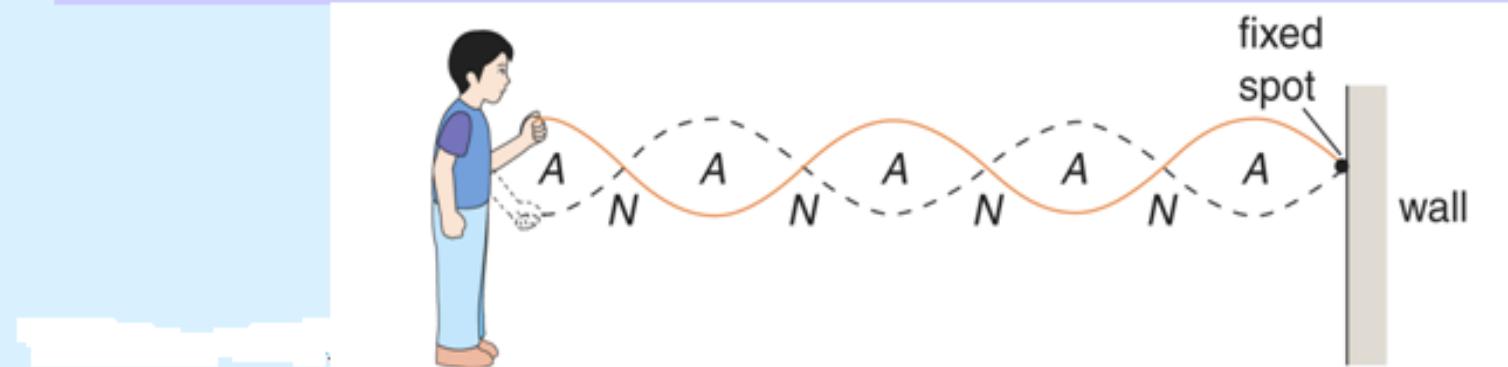

Stationary waves (standing waves) produced in

- string of guitar or piano
- rope (one end tie to wall)

- **Incident wave** is reflected by the wall to form **reflected wave**

- **superposition** of the waves produces stationary wave

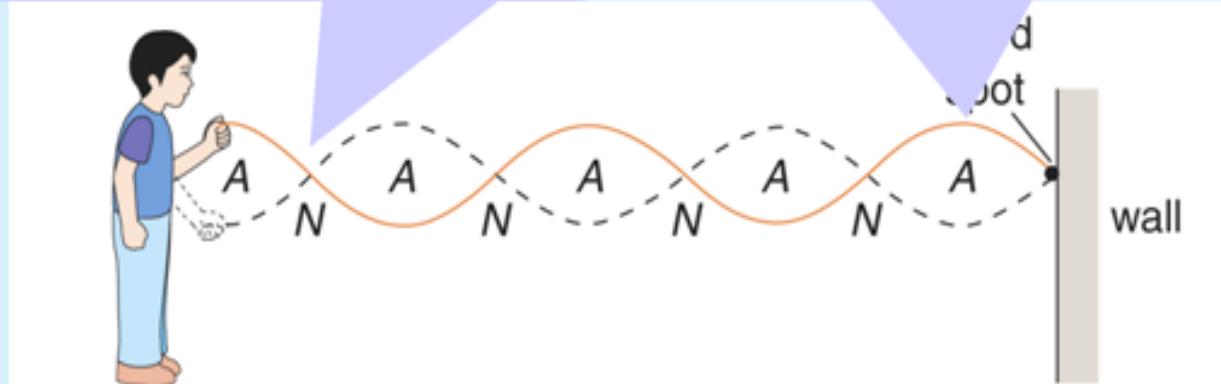

Introduction to stationary waves

N – **nodes** (remain stationary)

A – **antinodes**
(largest amplitude of oscillation)

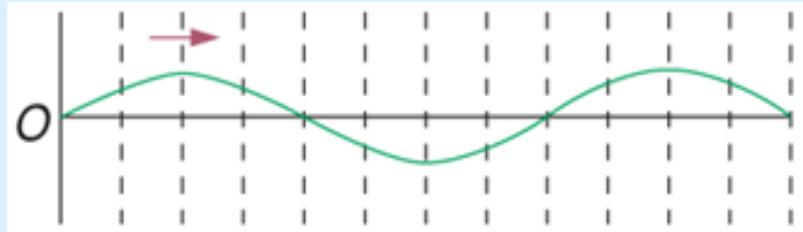

A stationary wave is produced by the superposition of two **progressive waves** of the same amplitude and frequency but travelling in opposite directions.

Introduction to stationary waves

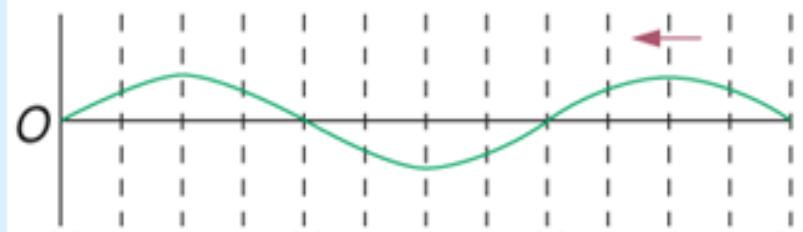

(a) at time t (**constructive interference**)

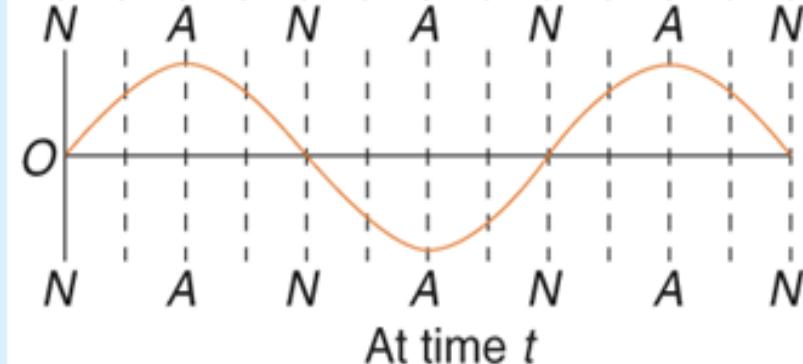

(1) To right

(2) To left

(1) + (2) = (3)

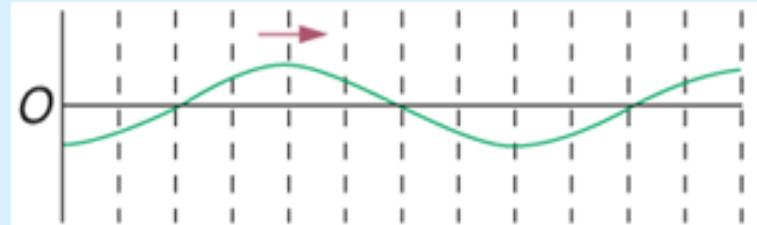

Introduction to stationary waves

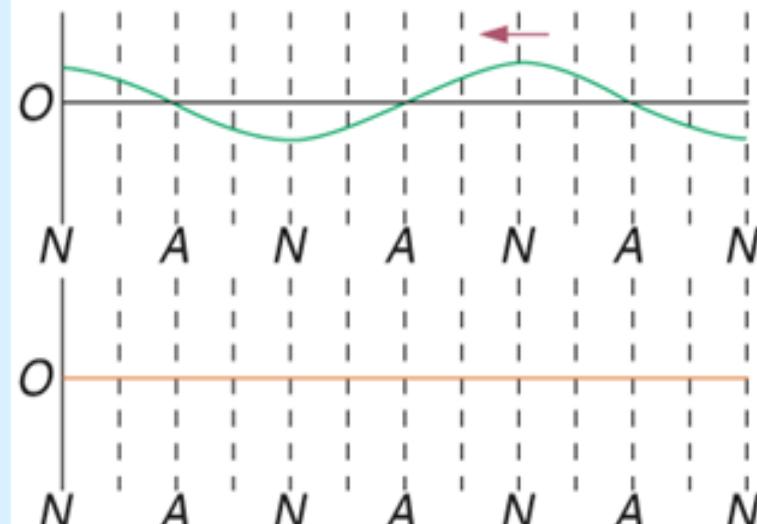

(b) at time $t + T/4$ (destructive interference)

(1)

(2)

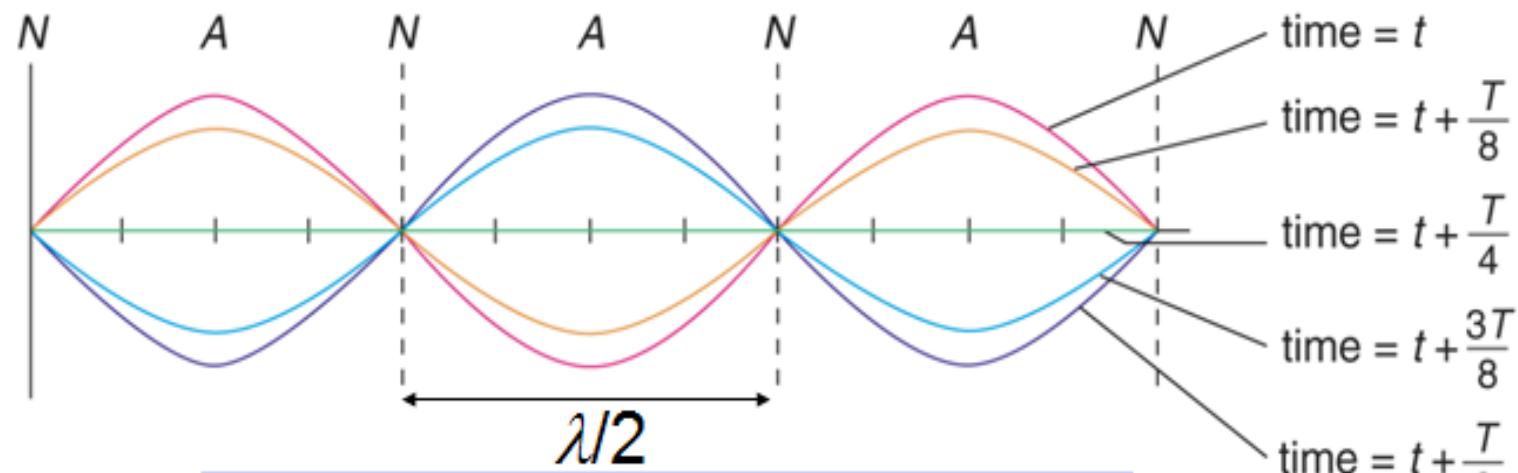

(1) + (2) = (3)

At time $t + \frac{T}{4}$

Introduction to stationary waves

Vibration of stationary wave at various instants

$$y_1 = a \sin\left(\omega t - \frac{2\pi x}{\lambda}\right), \quad y_2 = a \sin\left(\omega t + \frac{2\pi x}{\lambda}\right)$$

$$y = y_1 + y_2 = \left(2a \cos \frac{2\pi x}{\lambda}\right) \sin \omega t$$

Amplitude (A) of resultant stationary wave

The positions of antinodes

Progressive wave	Stationary wave
Energy is transferred along the direction of propagation.	No energy is transferred along the direction of propagation.
The wave profile moves in the direction of propagation.	The wave profile does not move in the direction of propagation.
Every point along the direction of propagation is displaced.	There are points known as nodes where no displacement occurs.
Every point has the same amplitude.	Points between two successive nodes have different amplitudes.
Neighbouring points are not in phase.	All points between two successive nodes vibrate in phase with one other.

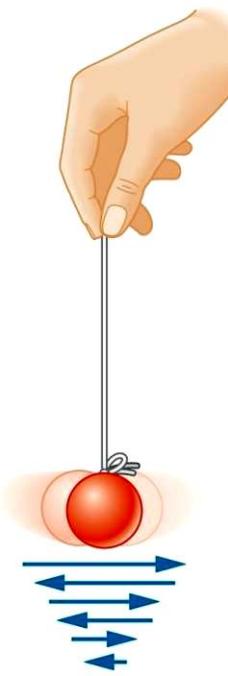

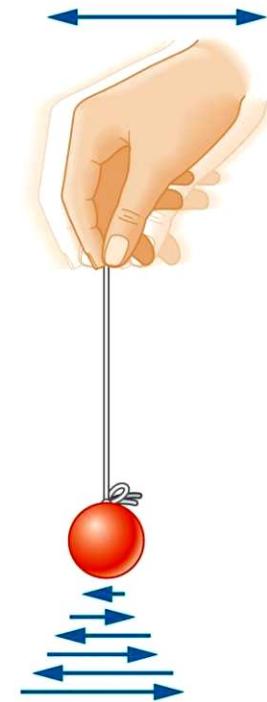

Forced Oscillations; Resonance

Forced vibrations occur when there is a periodic driving force. This force may or may not have the same period as the natural frequency of the system.

If the frequency is the same as the natural frequency, the amplitude can become quite large. This is called resonance.

Figure : Caption: (a) Large-amplitude oscillations of the Tacoma Narrows Bridge, due to gusty winds, led to its collapse (1940). (b) Collapse of a freeway in California, due to the 1989 earthquake.

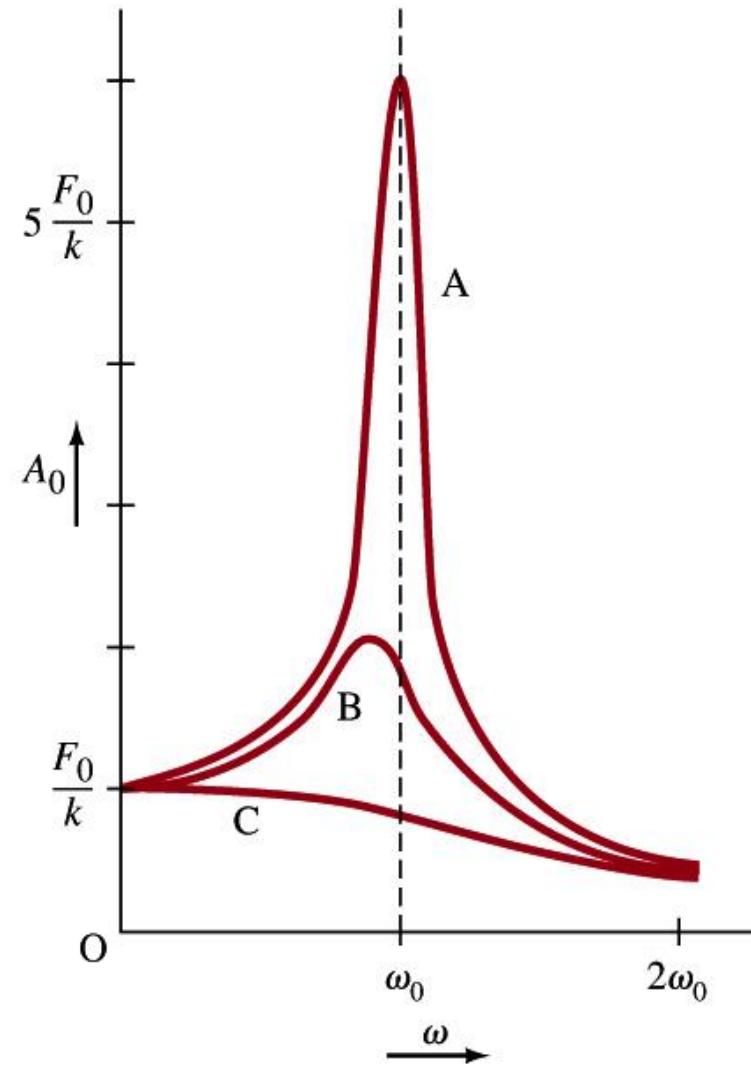

Equation of Driven Harmonic Motion.

- Consider what happens when we apply a time-dependent force $F(t)$ to a system that normally would carry out SHM with an angular frequency ω_0 .
- Assume the external force $F(t) = mF_0\sin(\omega t)$. The equation of motion can now be written as

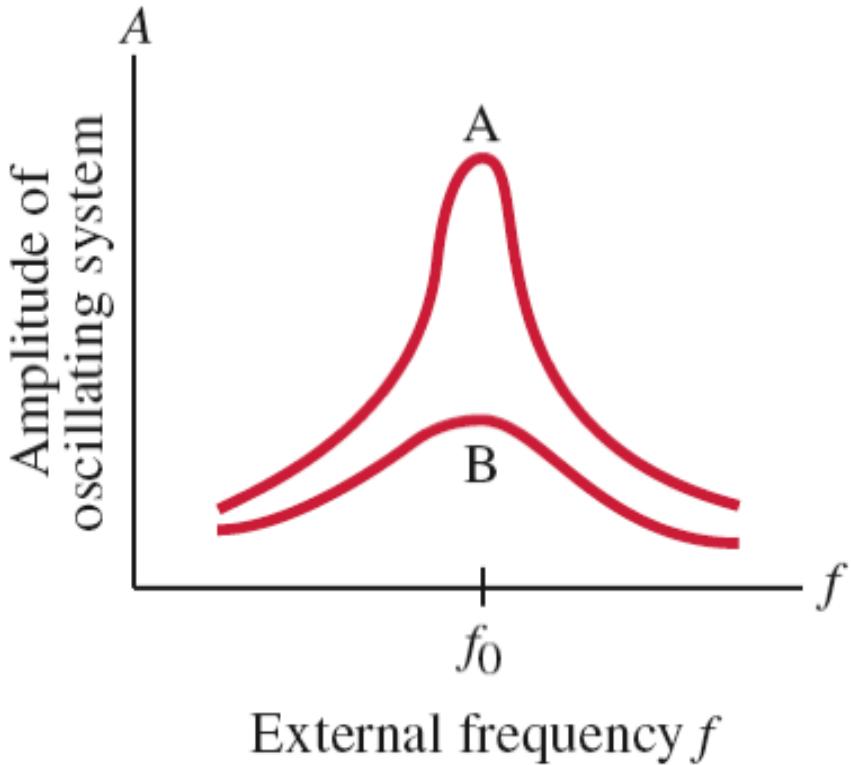

$$\frac{d^2x}{dt^2} = -\omega_0^2 x + F_0 \sin(\omega t)$$

- The steady state motion of this system will be harmonic motion with an angular frequency equal to the angular frequency of the driving force.

- If the driving force has a frequency close to the natural frequency of the system, the resulting amplitudes can be very large even for small driving amplitudes. The system is said to be in resonance.
- In realistic systems, there will also be a damping force. Whether or not resonance behavior will be observed will depend on the strength of the damping term.

Forced Oscillations; Resonance

The sharpness of the resonant peak depends on the damping. If the damping is small (A) it can be quite sharp; if the damping is larger (B) it is less sharp.

Like damping, resonance can be wanted or unwanted.
Musical instruments and TV/radio receivers depend on it.

Forced Oscillations; Resonance

The equation of motion for a forced oscillator is:

$$ma = -kx - bv + F_0 \cos \omega t.$$

The solution is: $x = A_0 \sin(\omega t + \phi_0)$,

where $A_0 = \frac{F_0}{m \sqrt{(\omega^2 - \omega_0^2)^2 + b^2 \omega^2 / m^2}}$

and

$$\phi_0 = \tan^{-1} \frac{\omega_0^2 - \omega^2}{\omega(b/m)}.$$

Forced Oscillations; Resonance

The width of the resonant peak can be characterized by the Q factor:

$$Q = \frac{m\omega_0}{b}.$$
